

Presentation on the theme: coral reefs

did: Salenko Egor and Heitkulov Gleb

0 Coral looks like rock, but it is actually a huge collection of tiny clear animals called coral polyps. The bright colour of coral comes from tiny sea plants called algae.

0 Coral and algae depend on each other to live. Coral may feel tough but it is very sensitive. today, many coral reefs are dying and there are many reasons why.

0 First of all, the oceans are getting warmer. This kills the algae and so the coral reefs lose their color and food

0 Water pollution , fishing with dynamite as well as the careless collection of coral also hurt coral reef. If we do not take action, all the reefs will die in around 20 years

o This will lead thousands of sea creatures to extinction. We can help save the world is coral reefs by joining an environmental organization like Reef Relief/ it is worth a try!

~~Thanks for attention~~
