Fibromyalgia

What is fibromyalgia?

The term fibromyalgia means pain in fibrous and muscular tissues. It is a chronic (ongoing) condition of pain, stiffness, and usually fatigue.

Fibromyalgia affects several million people in the US. It is more common in younger adults, and more women have it than men.

How does it occur?

What fibromyalgia is exactly, or what causes it, is not known. Studies have shown that many people with the condition have abnormal brain waves (EEGs) during sleep. Others have less of the hormone called cortisol. Stress, anxiety, depression, illness, or poor sleep may contribute to the problem. The symptoms may get worse when you overexert yourself or when the weather is damp and cold.

Classification:

- Antimicrobial Agents
- Macrolides

Description: Azithromycin is a semisynthetic antibiotic belonging to the macrolide subgroup of azalides and is similar in structure to erythromycin. Although azithromycin is significantly more expensive, it can be dosed once daily and produces less GI intolerance than does erythromycin. An apparent advantage over erythromycin is that azithromycin reaches higher intracellular concentrations, thus increasing its efficacy and duration of action. These advantages are demonstrated in studies comparing the two antibiotics in the treatment of various infections.
