Australia. // Journal of the
Geological Society of
Australia, 1983. 30:
149-153.

Fig. 1. Map of the eastern Yilgarn Block of Western Australia, showing the gneiss localities.

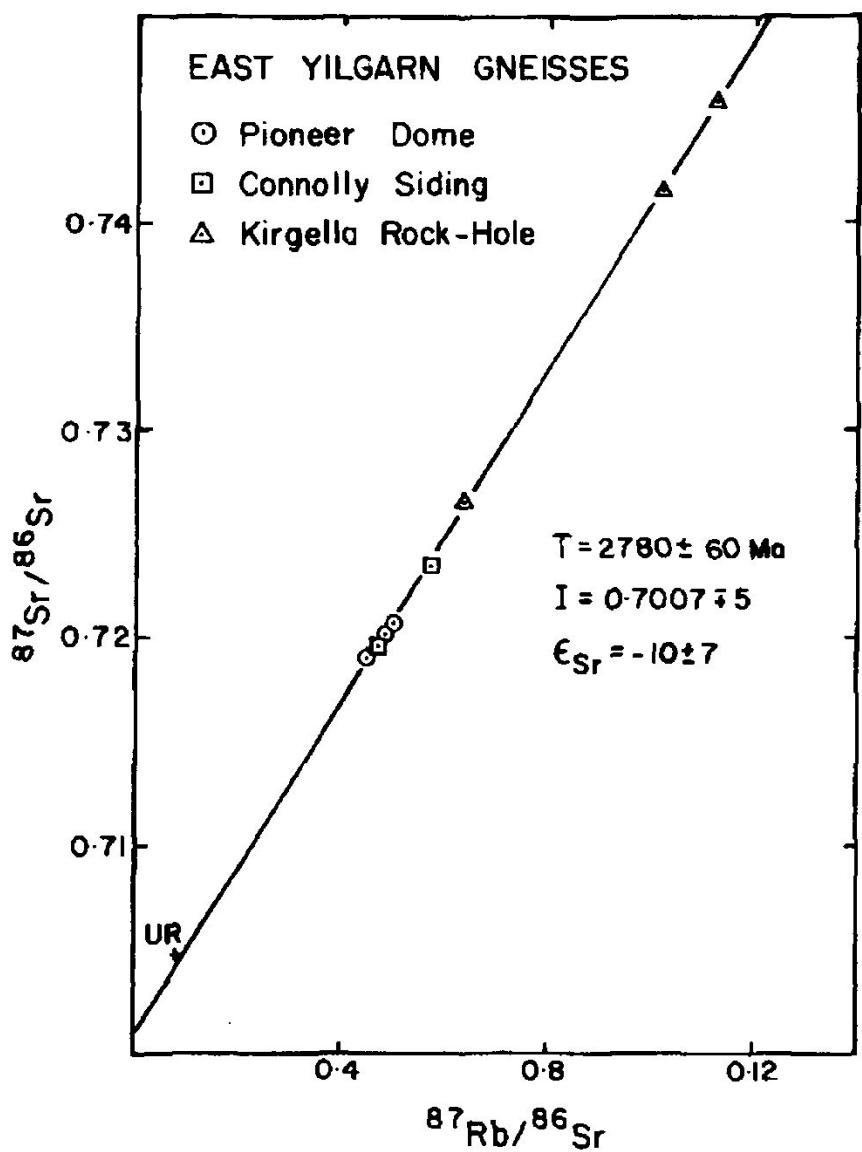

Fig. 2. Rb-Sr whole-rock isochron for the eastern Yilgarn gneisses. Despite the regional sampling, all points lie close to a single line. The cross shows the present-day bulk earth point (UR).

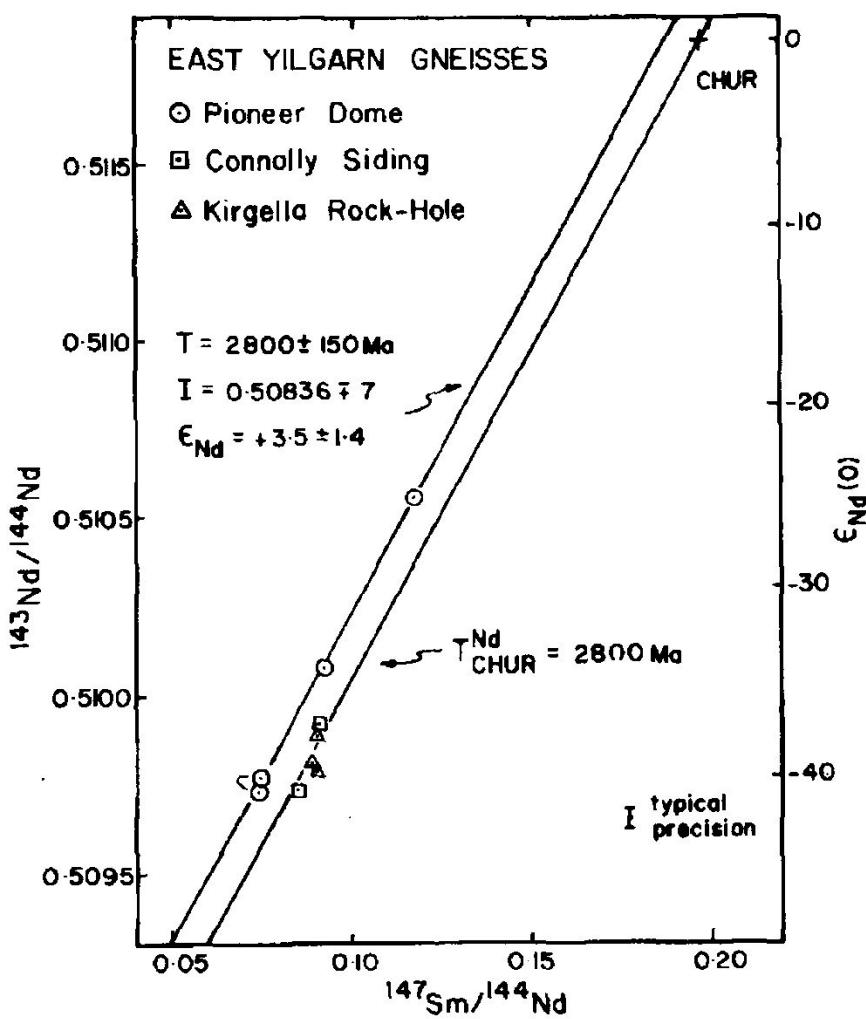

Fig. 3. Sm-Nd isochron diagram for the eastern Yilgarn gneisses. In contrast to Rb-Sr, the points do not define a single array, although individual localities form broadly coherent groups. This disparity is consistent with the Pioneer Dome gneisses being derived from a depleted Nd/Sm source at c. 2800 Ma, whereas the Connolly Siding and Kirgella Rock-hole gneisses were derived from a chondritic Nd/Sm source (CHUR) at approximately the same time. The cross shows the present-day bulk earth point (CHUR).

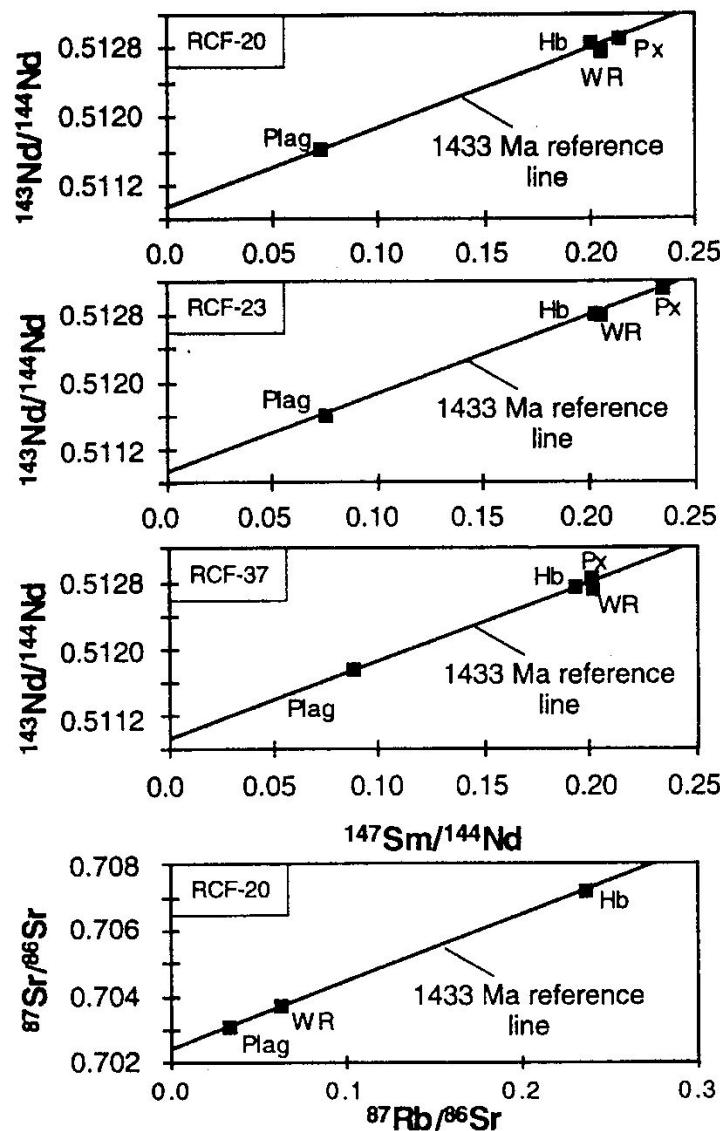

Figure 10. Sm-Nd and Rb-Sr mineral isochrons for metabasite samples RCF-20, RCF-23 and RCF-37. Isochron fits using the ISOPLOT program (Ludwig 1989) gave the following results: RCF-20 Sm-Nd = 1.40 ± 0.23 Ga, MSWD = 37; RCF-23 Sm-Nd = 1433 ± 17 Ma, MSWD = 1.0; RCF-37 Sm-Nd = 1.40 ± 0.23 Ga, MSWD = 23; RCF-20 Rb-Sr = 1385 ± 31 Ma, MSWD = 1.2. All errors are calculated at the 95% confidence level.

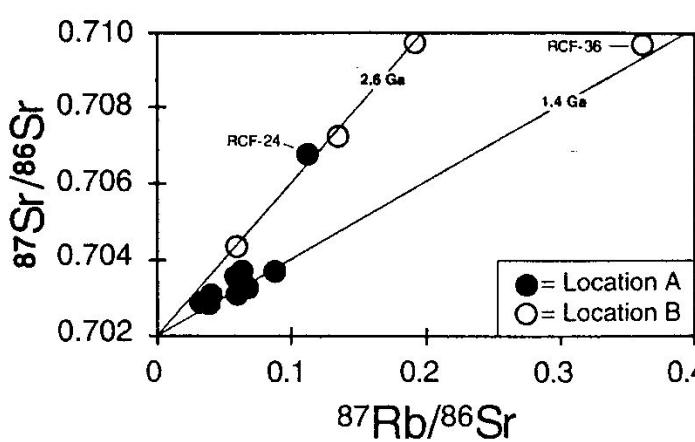

Figure 11. Rb-Sr isochron diagram for whole rock metabasite samples from Morton Pass. Samples containing more than 35% hornblende plot along a 2.6 Ga reference line, whereas samples in which greater amounts of hornblende has broken down plot near a 1.4 Ga reference line.

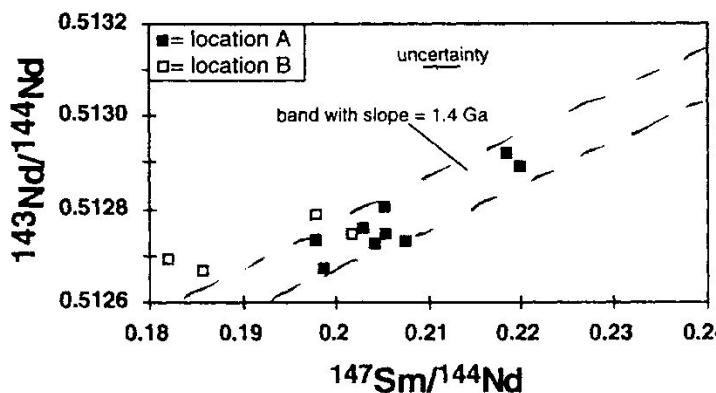

Figure 9. Sm-Nd whole rock isochron diagram for metabasites from location A (filled squares) and location B (open squares). The slope of the shaded band corresponds to an age of 1.4 Ga.

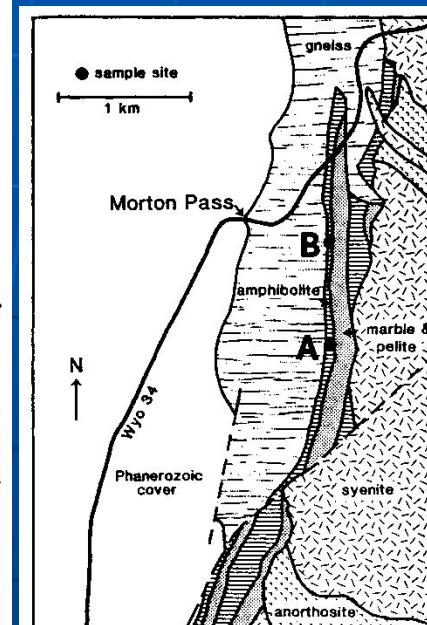

Figure 2. Geologic map of the Morton Pass area. Filled circles locate the two sample localities discussed in the text.

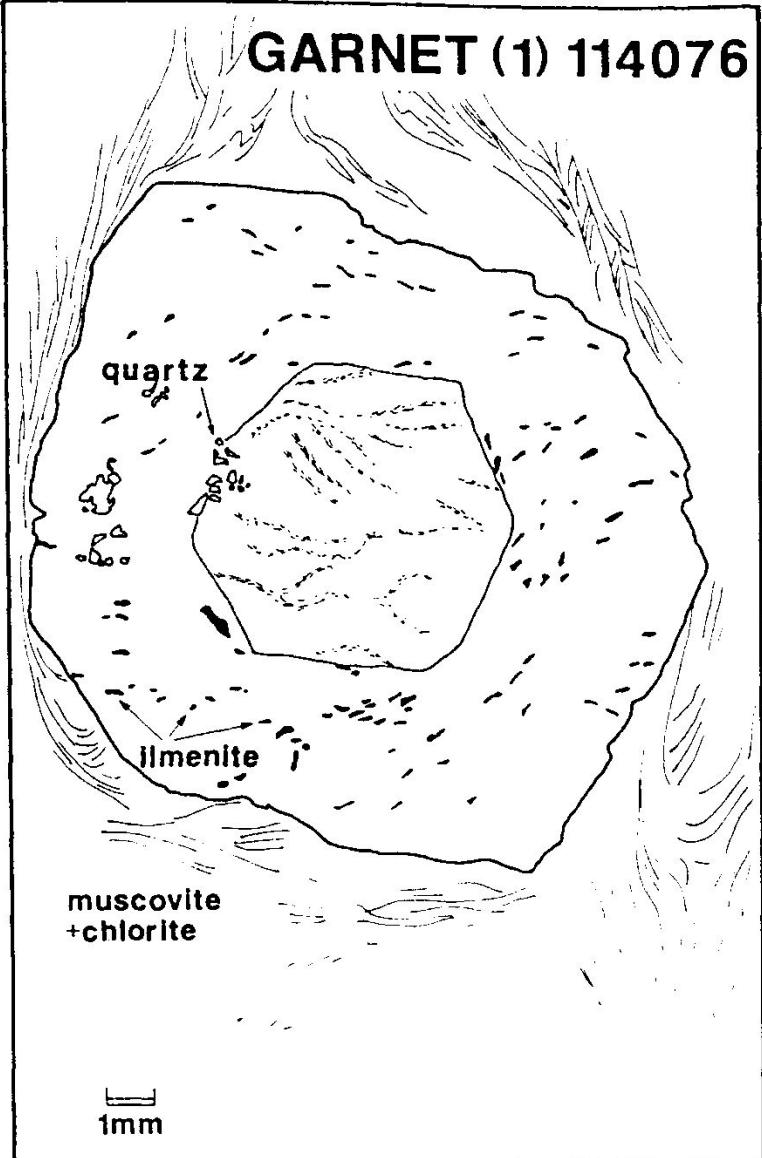

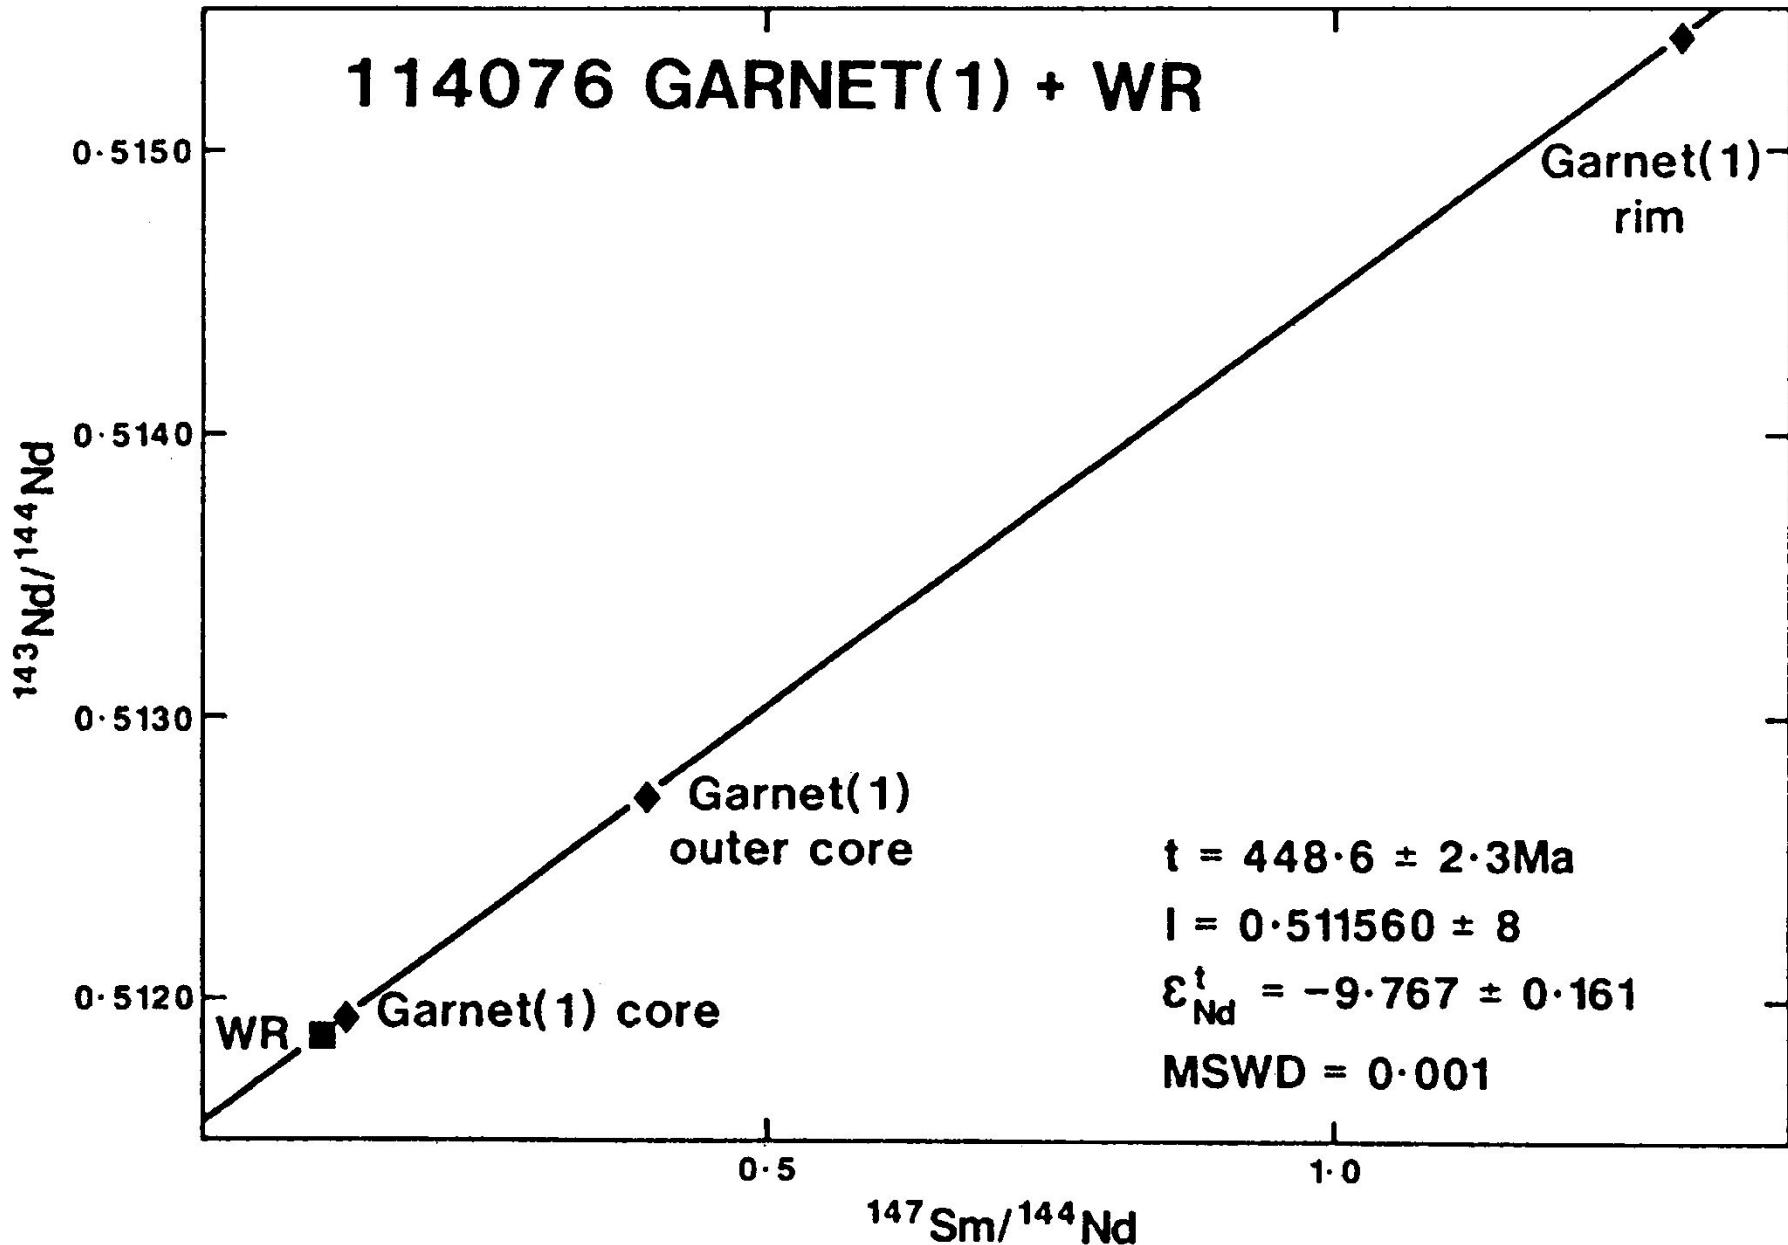

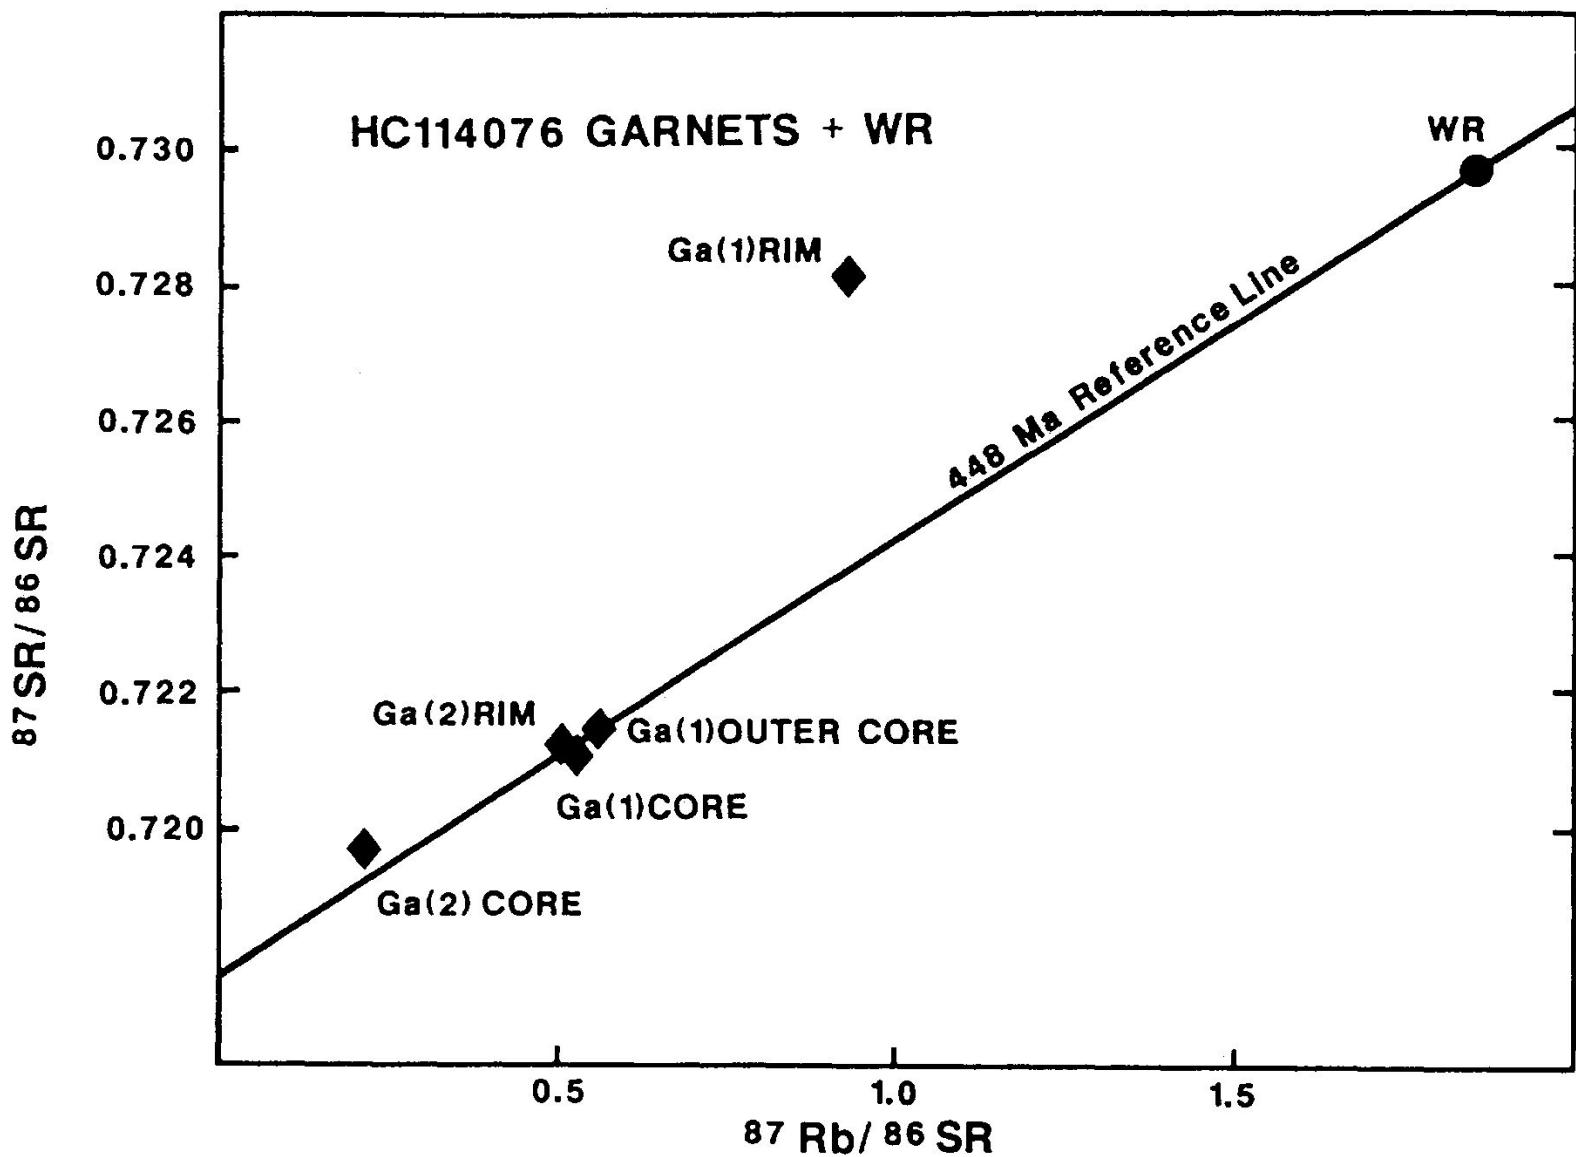

Fig. 1. Sketch of 114076 Garnet(1), Pigeon Island, Newfoundland, showing the inclusion-rich core containing needles of rutile and epidote < 50 μm long, and an optically clear outer core with 0.5 mm inclusions of ilmenite. The matrix is largely retrogressed to muscovite and chlorite.

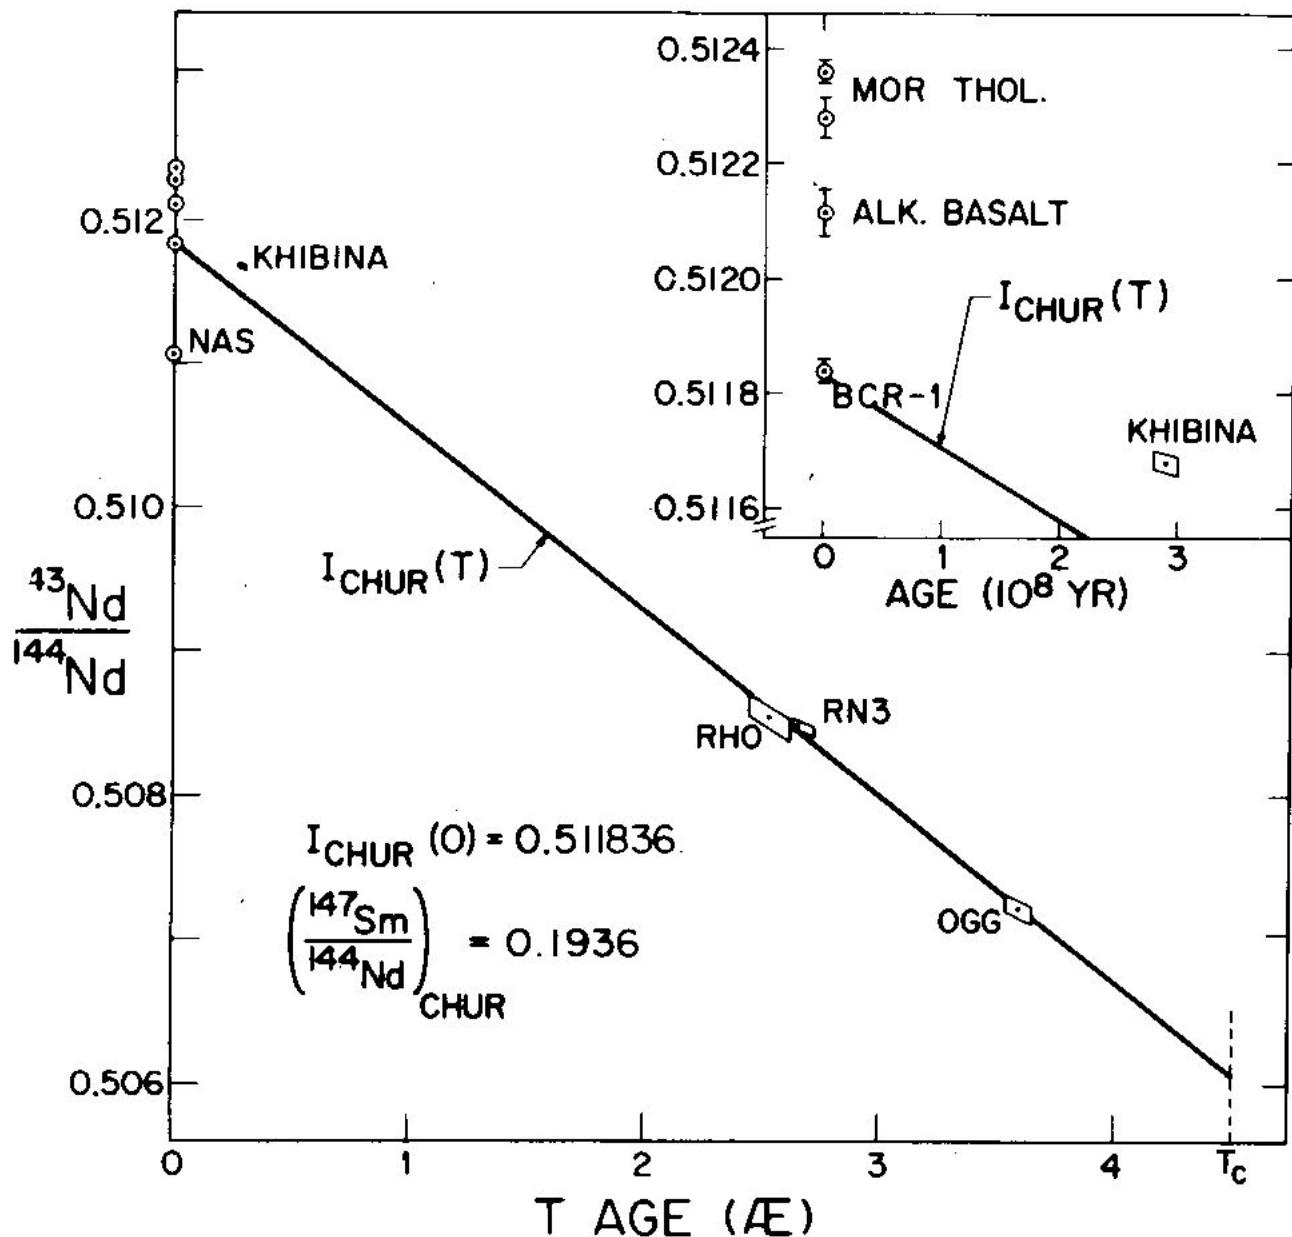

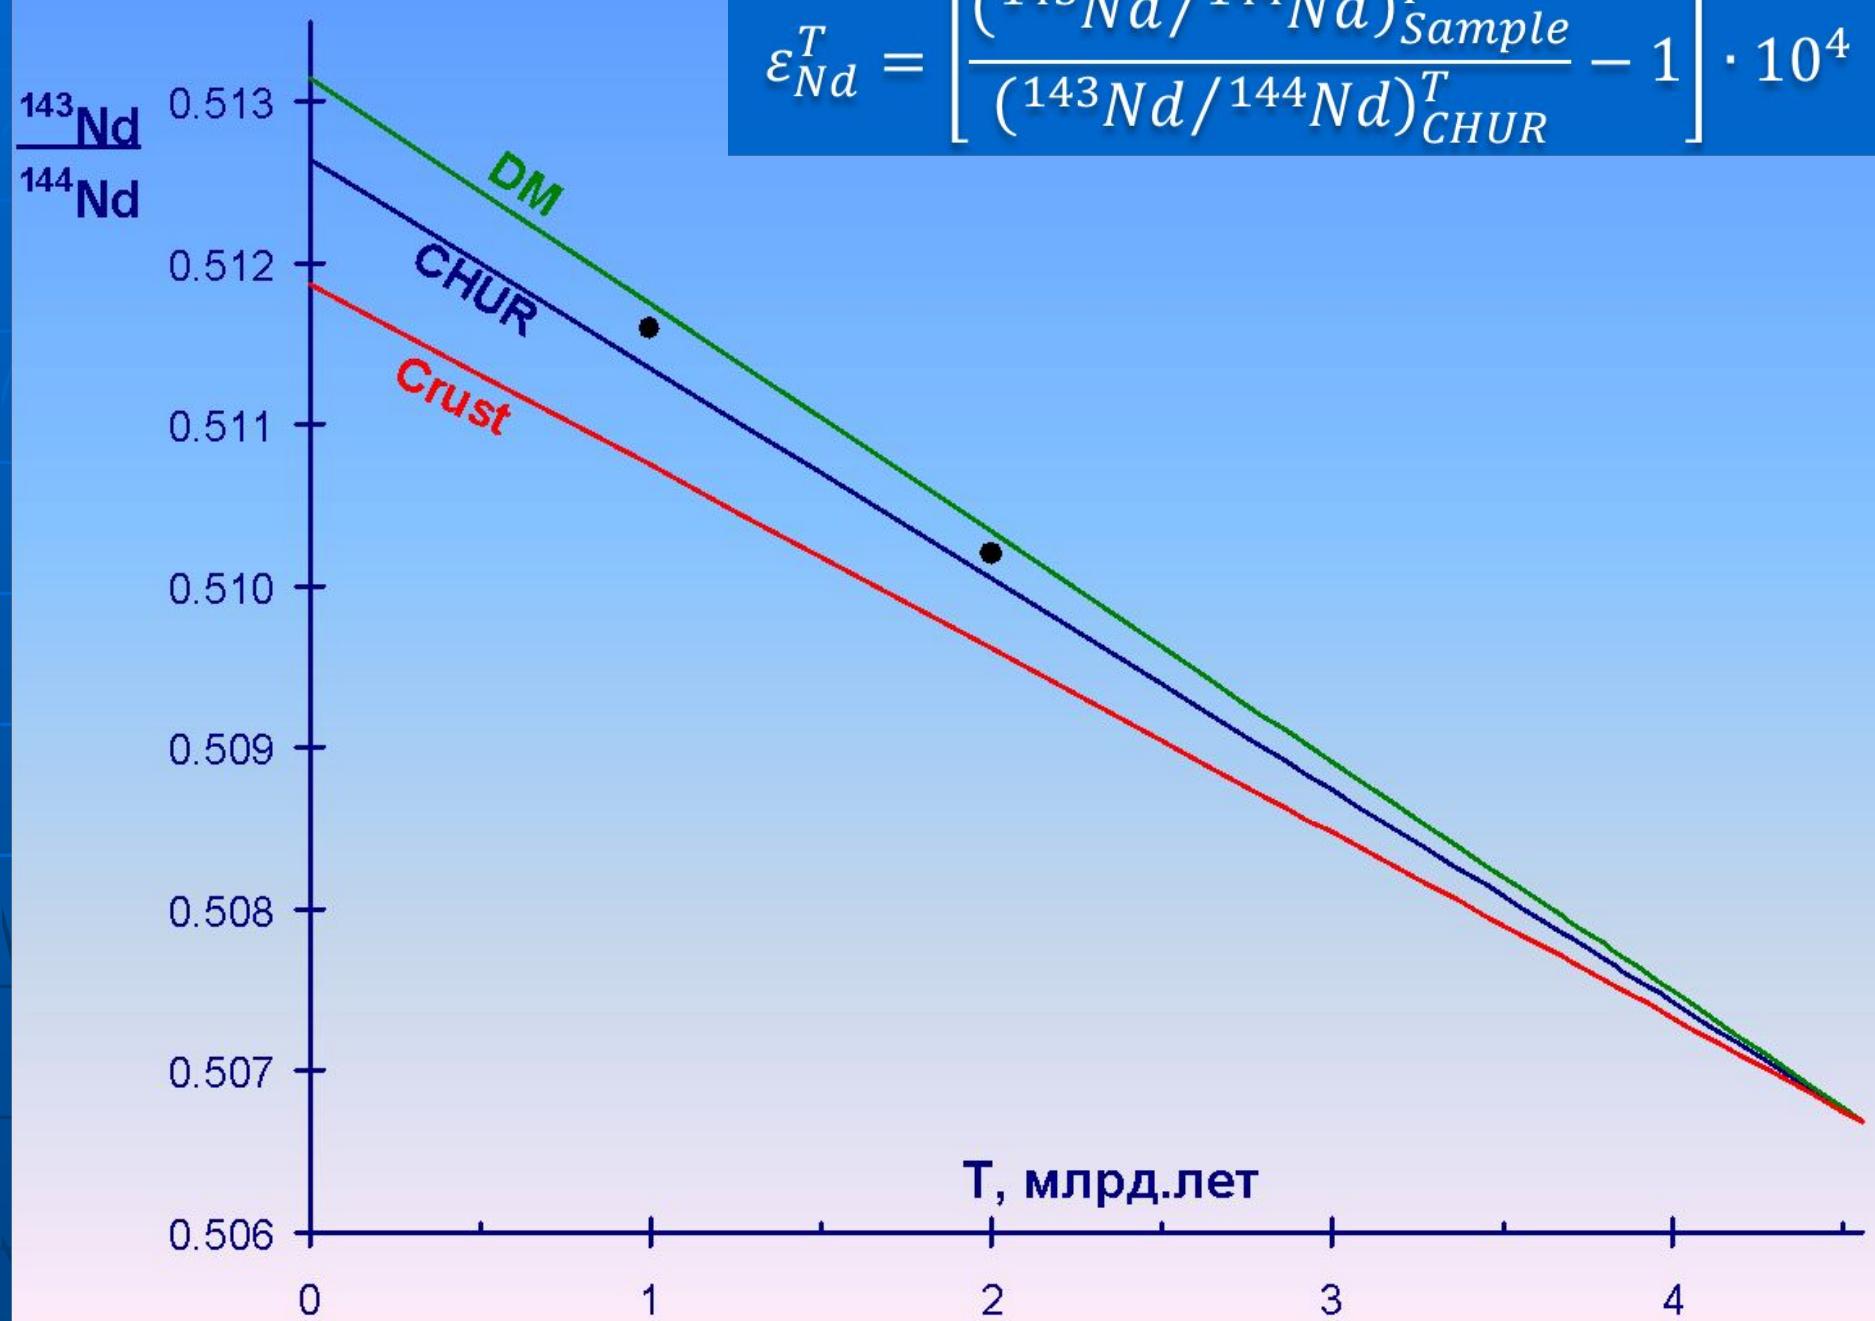

Fig. 2: Observed initial $^{143}\text{Nd}/^{144}\text{Nd}$ versus time. $I_{\text{CHUR}}(T)$ represents evolution of $^{143}\text{Nd}/^{144}\text{Nd}$ in a reservoir with chondritic Sm/Nd.

$$\varepsilon_{Nd}^T = \left[\frac{(^{143}Nd / ^{144}Nd)_{Sample}^T - 1}{(^{143}Nd / ^{144}Nd)_{CHUR}^T} \right] \cdot 10^4$$

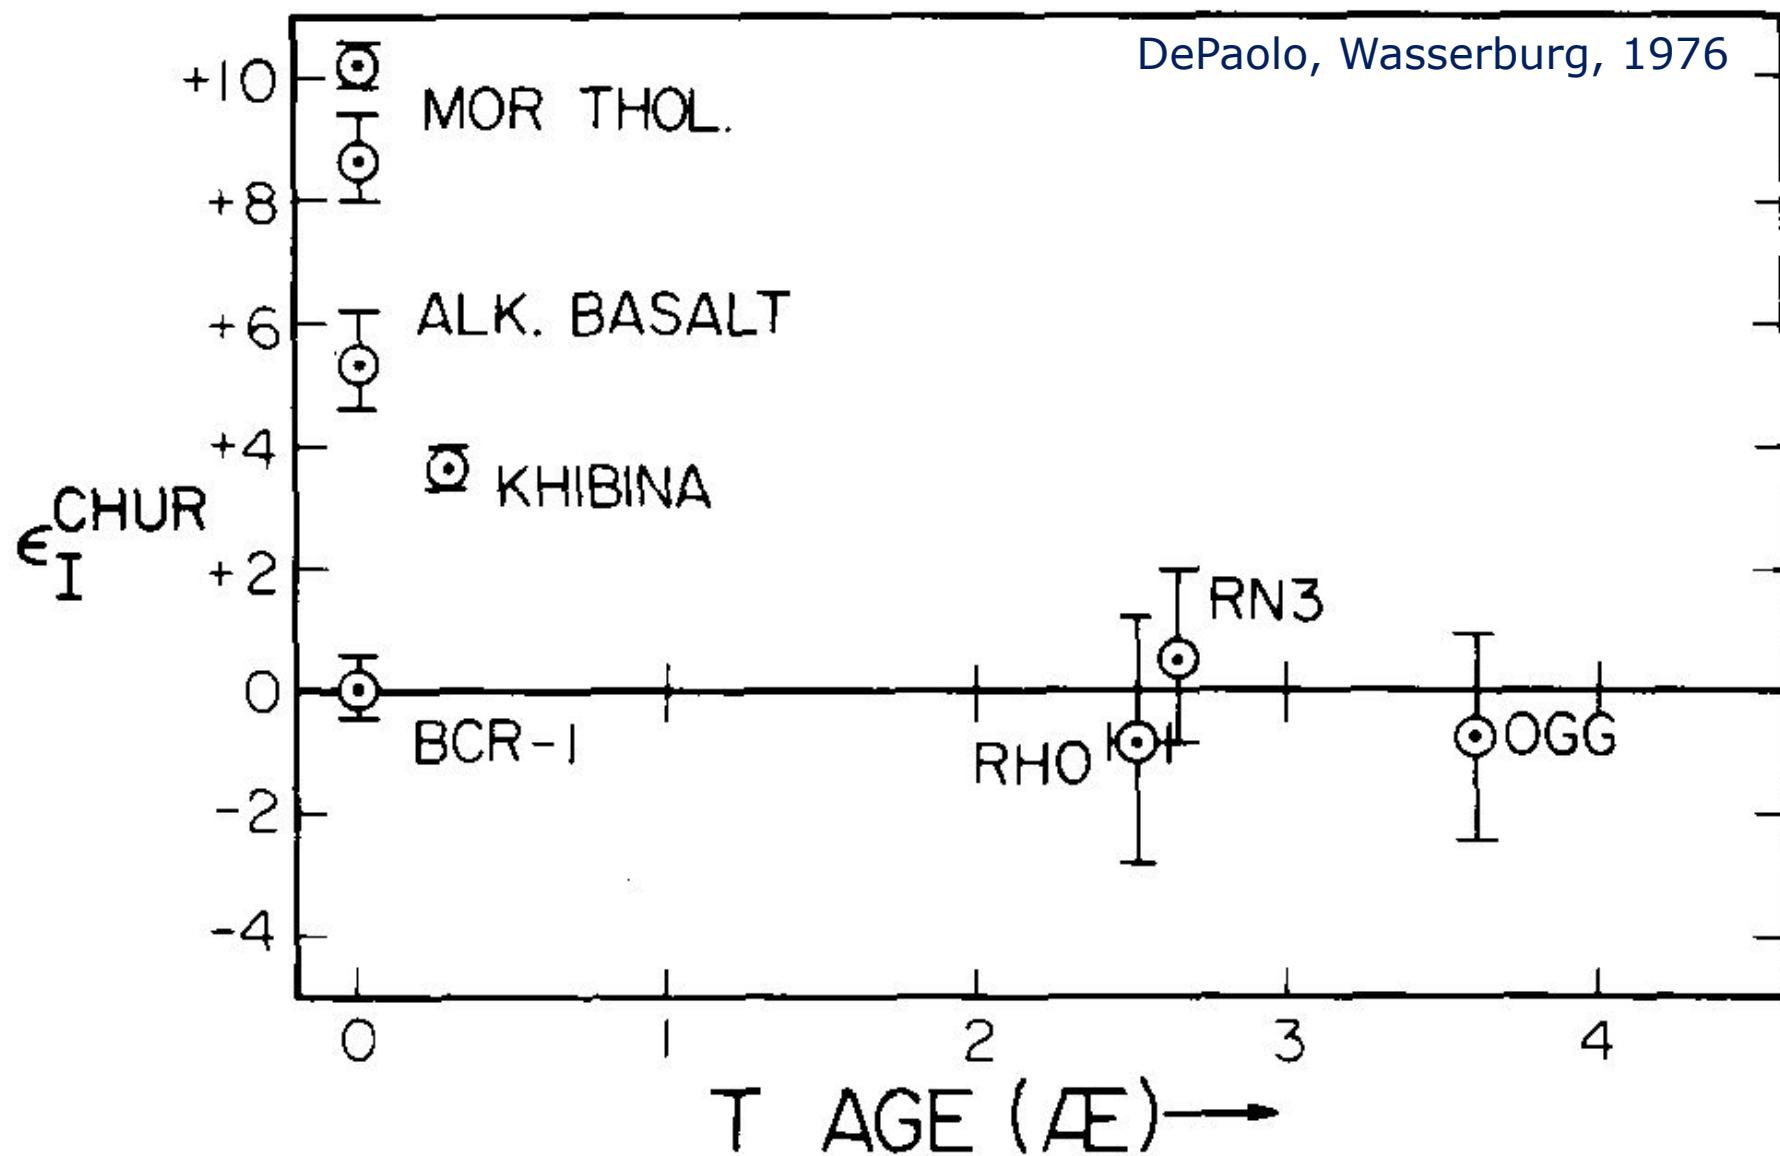

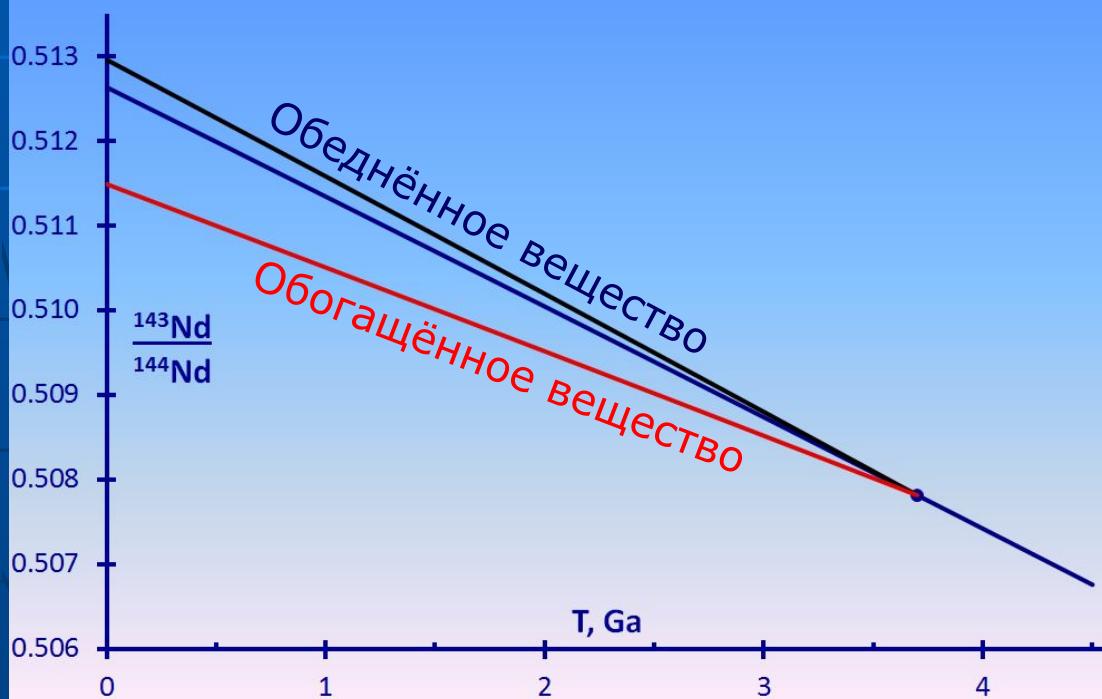

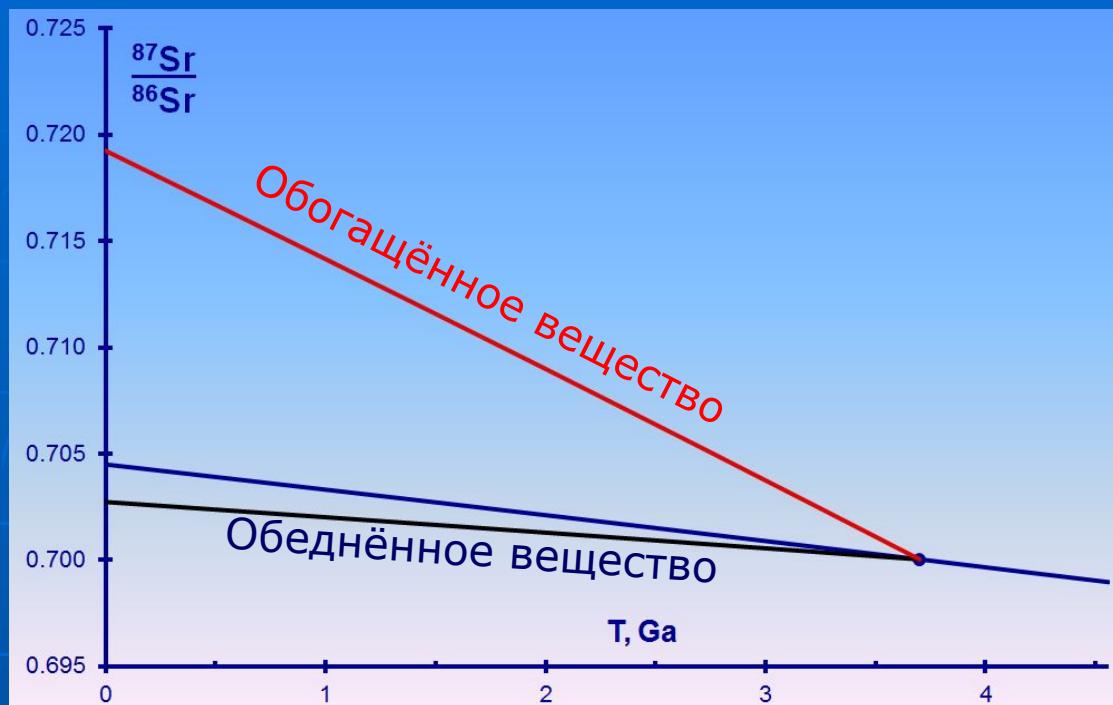

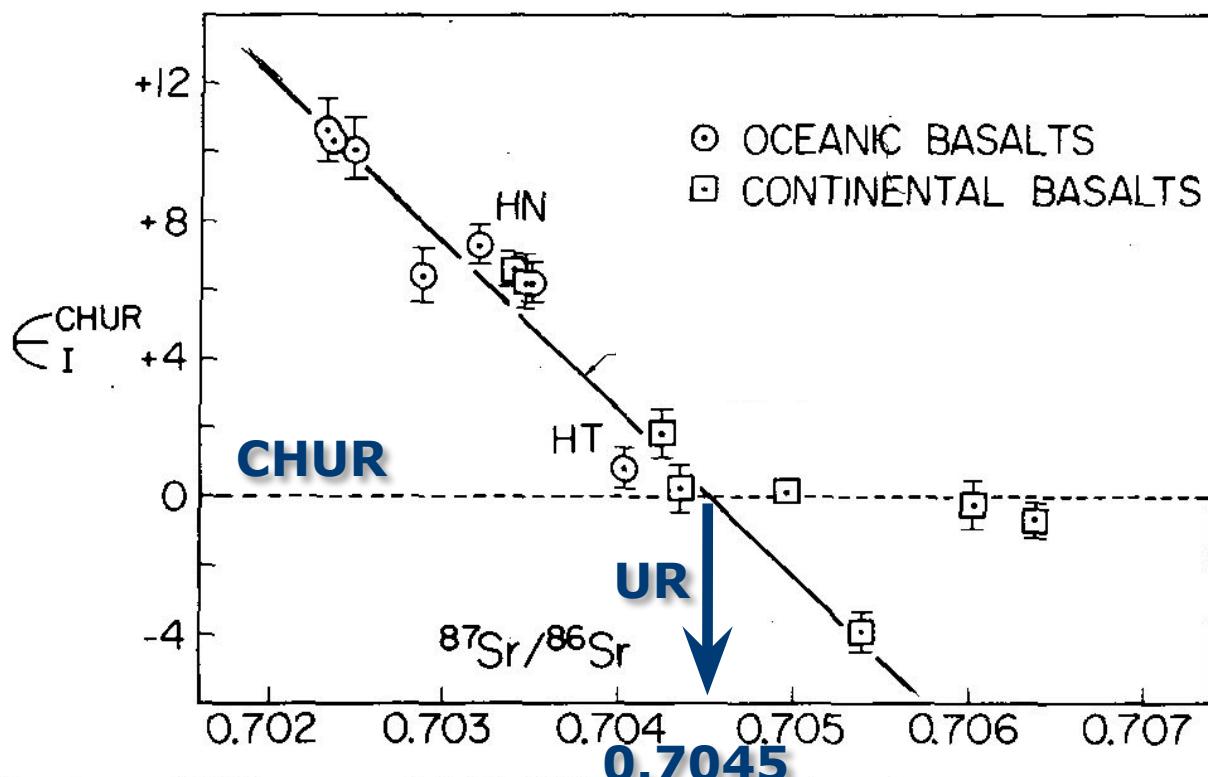

Fig. 3: Fractional deviations in parts in 10^4 of initial $^{143}\text{Nd}/^{144}\text{Nd}$ from evolution in a chondritic Sm/Nd reservoir (CHUR) vs. time.

DePaolo D.J., Wasserburg G.J. Inferences about magma sources and mantle structure from variations of $^{143}\text{Nd}/^{144}\text{Nd}$. // Geophysical Research Letters, 1976. 3(12): 743-746.

CHUR = Chondritic Uniform Reservoir

UR = Uniform Reservoir

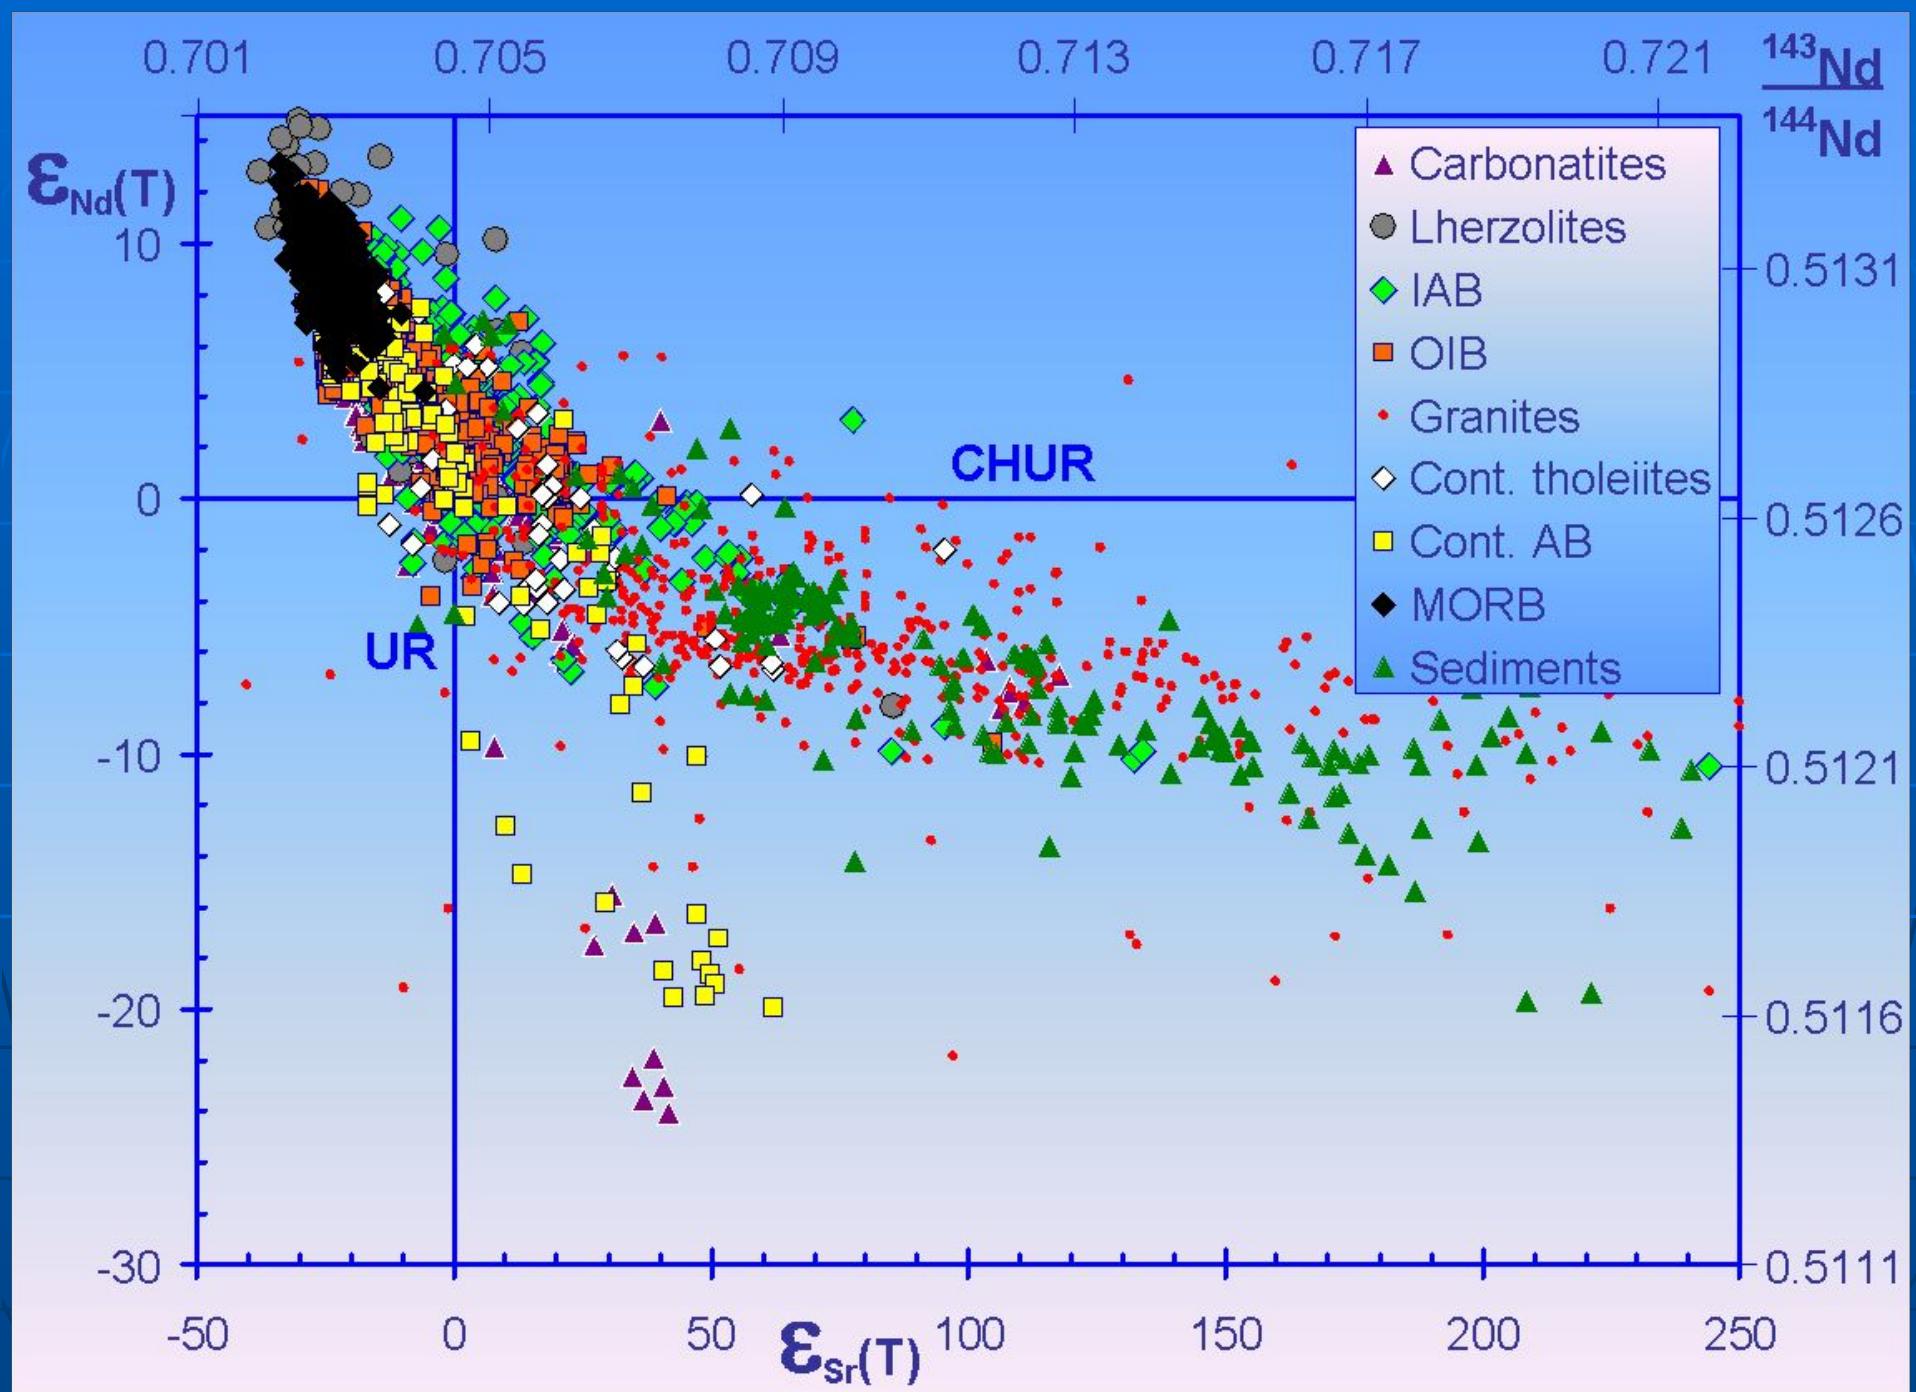

BSE = Bulk Silicate Earth

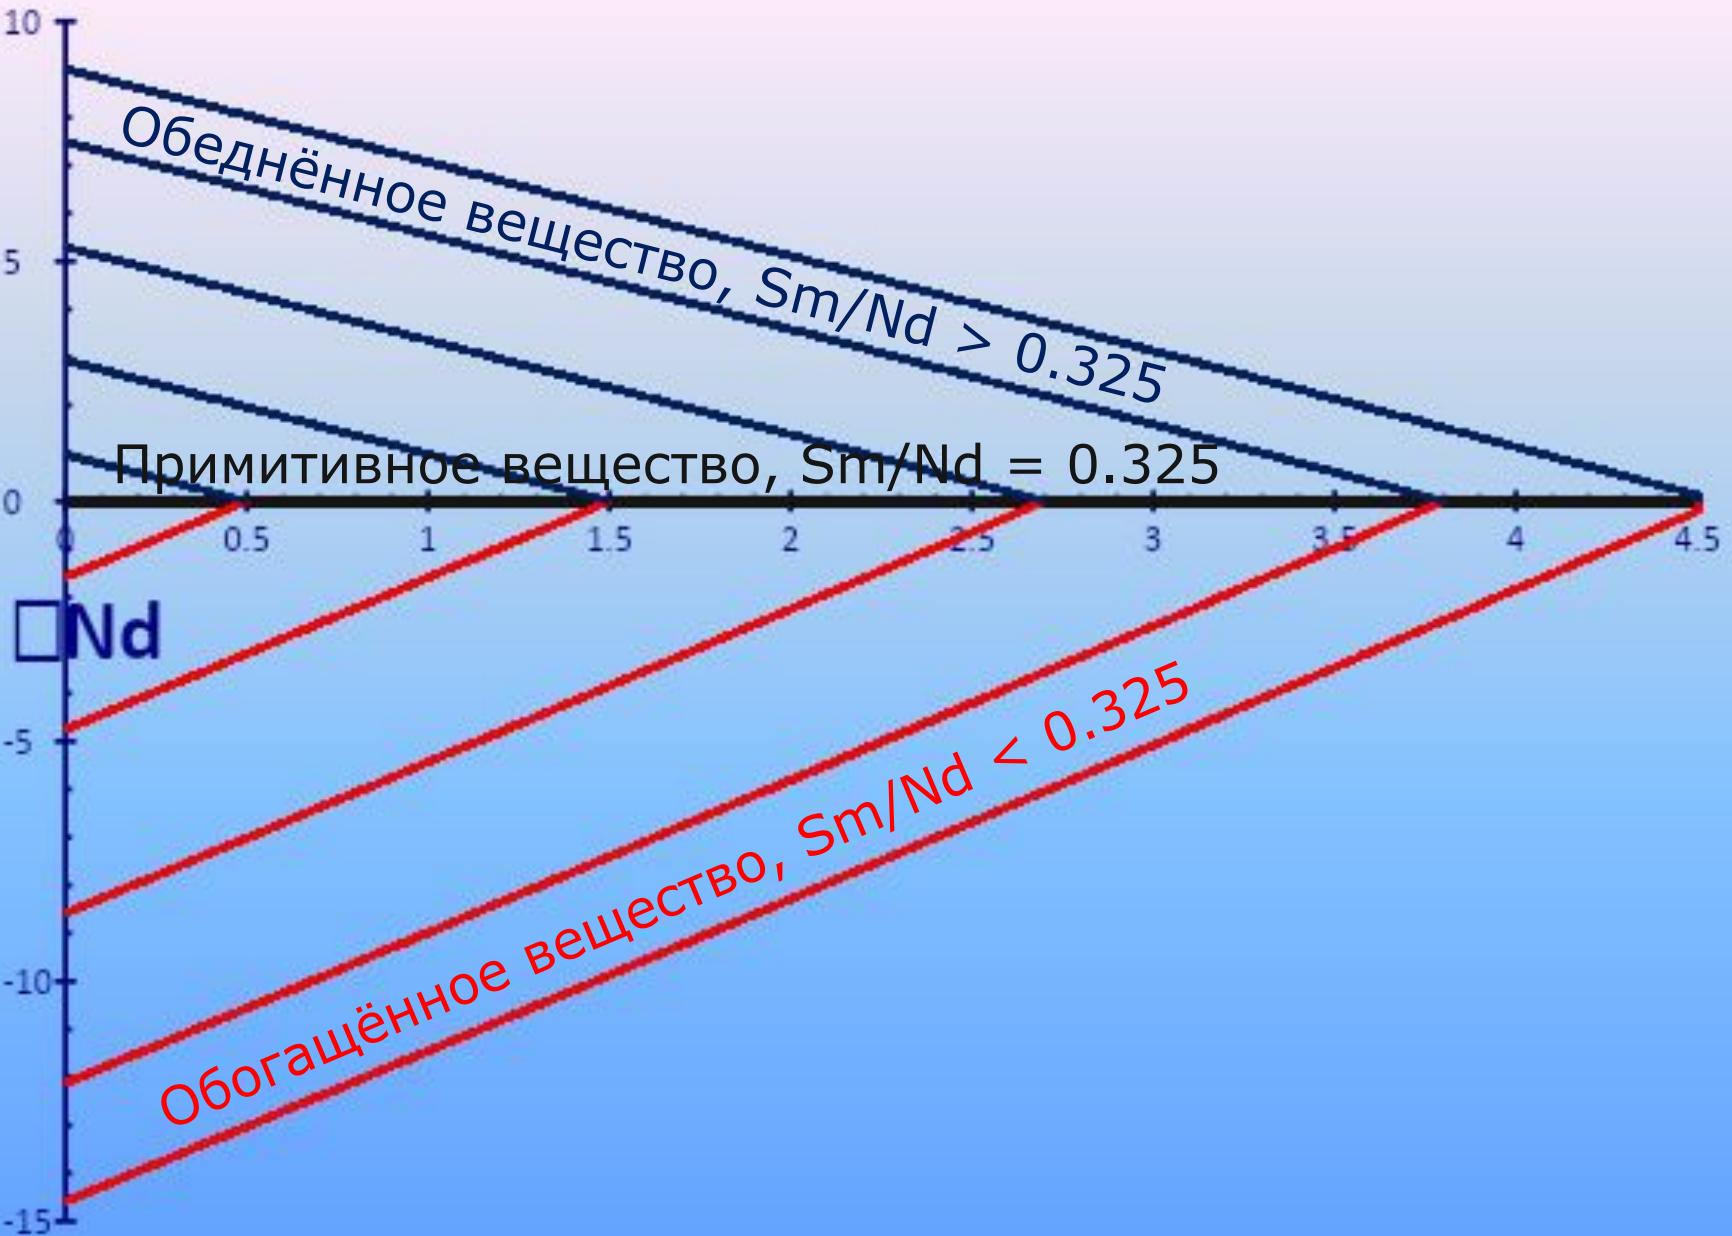

UR: $^{87}\text{Sr}/^{86}\text{Sr} = 0.7045$

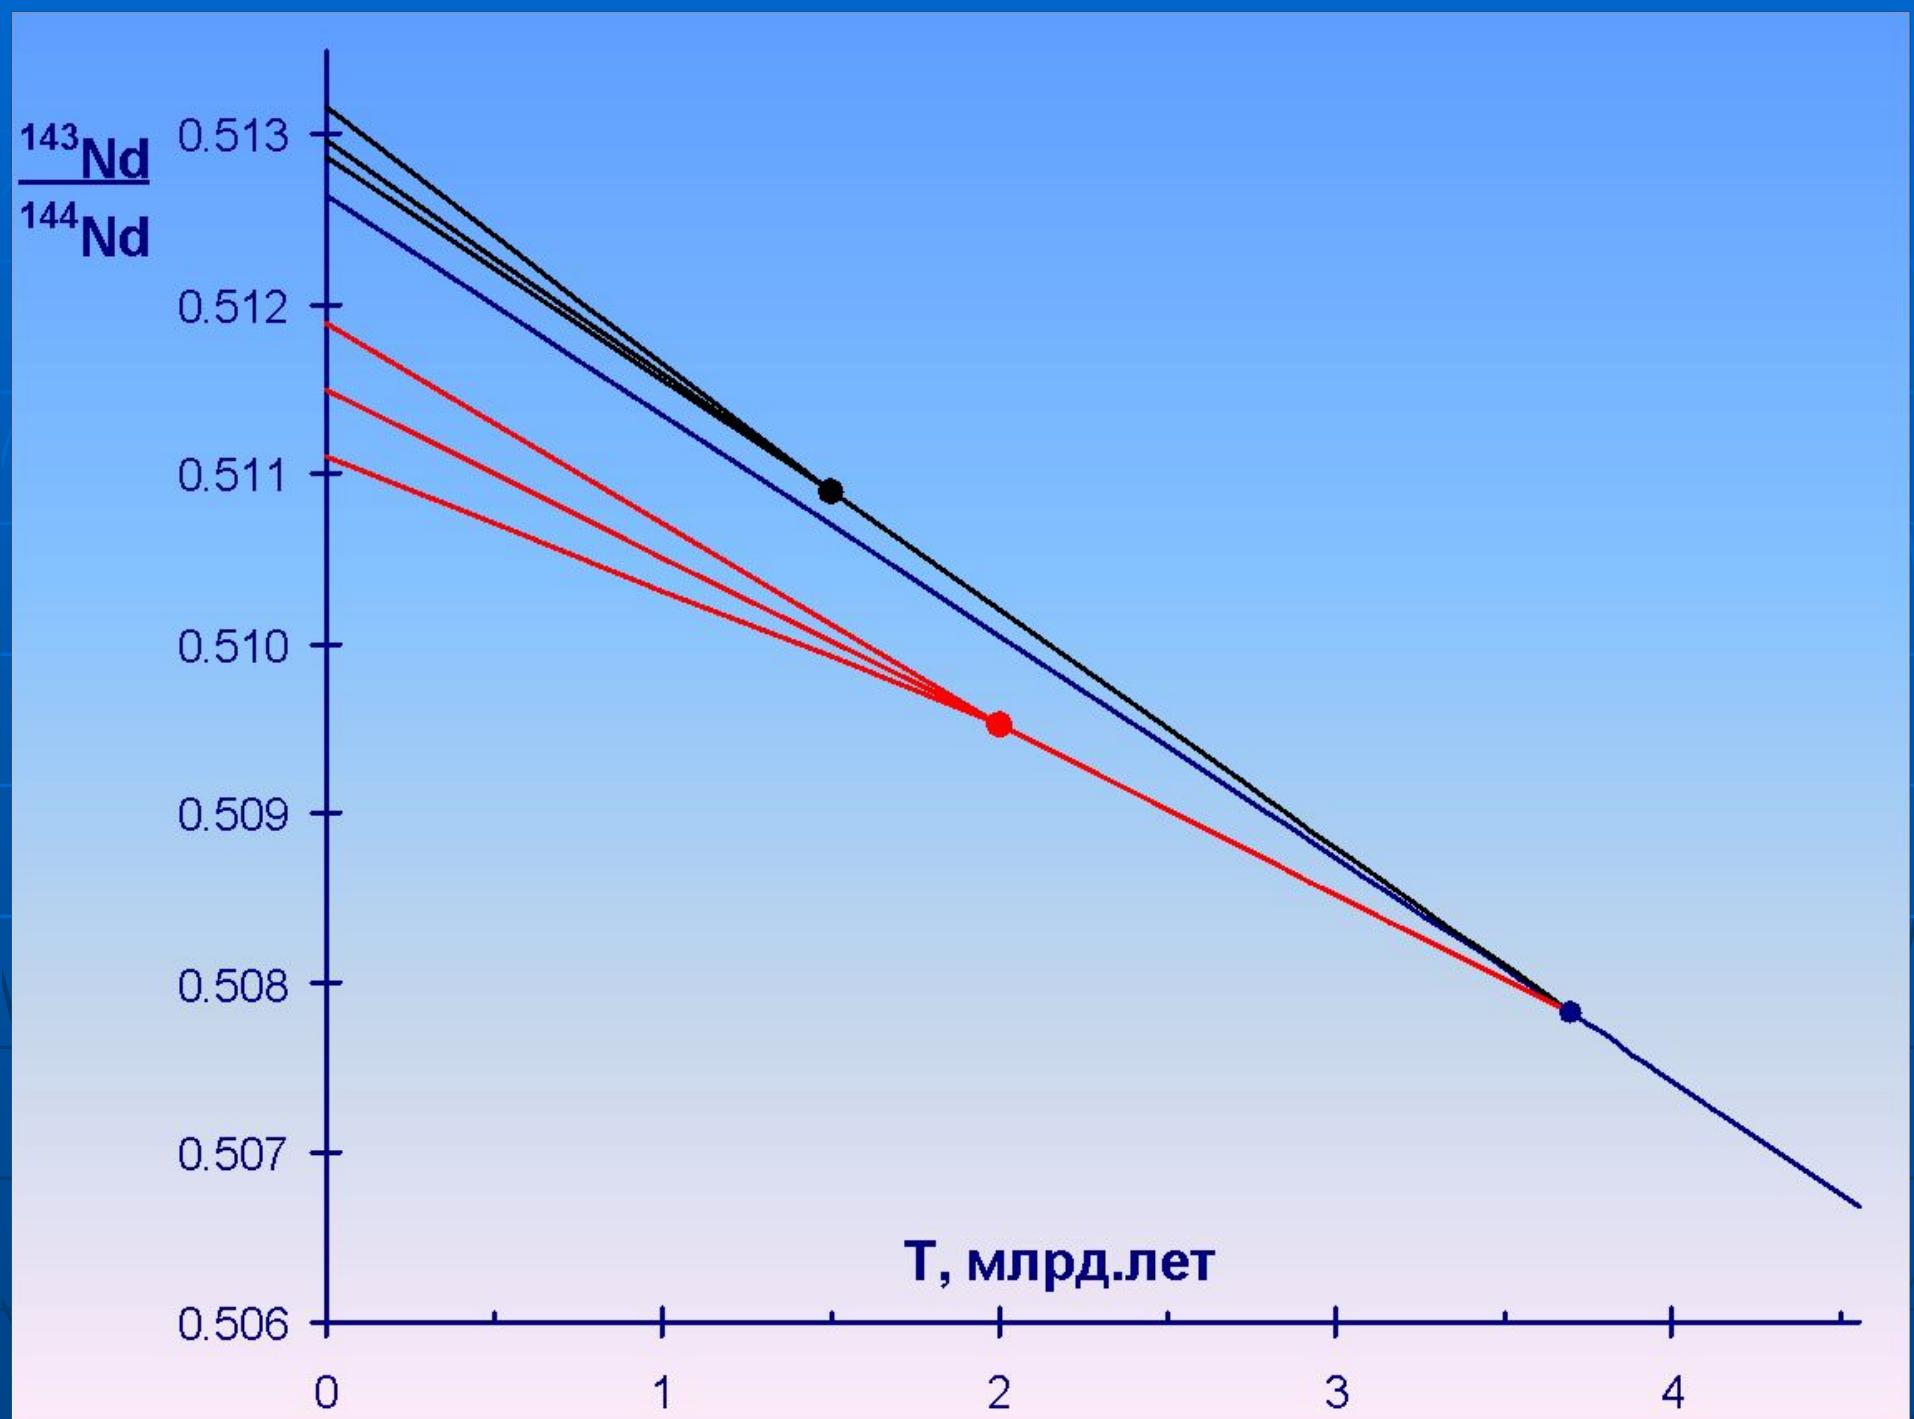

BABI: $^{87}\text{Sr}/^{86}\text{Sr} = 0.69897$

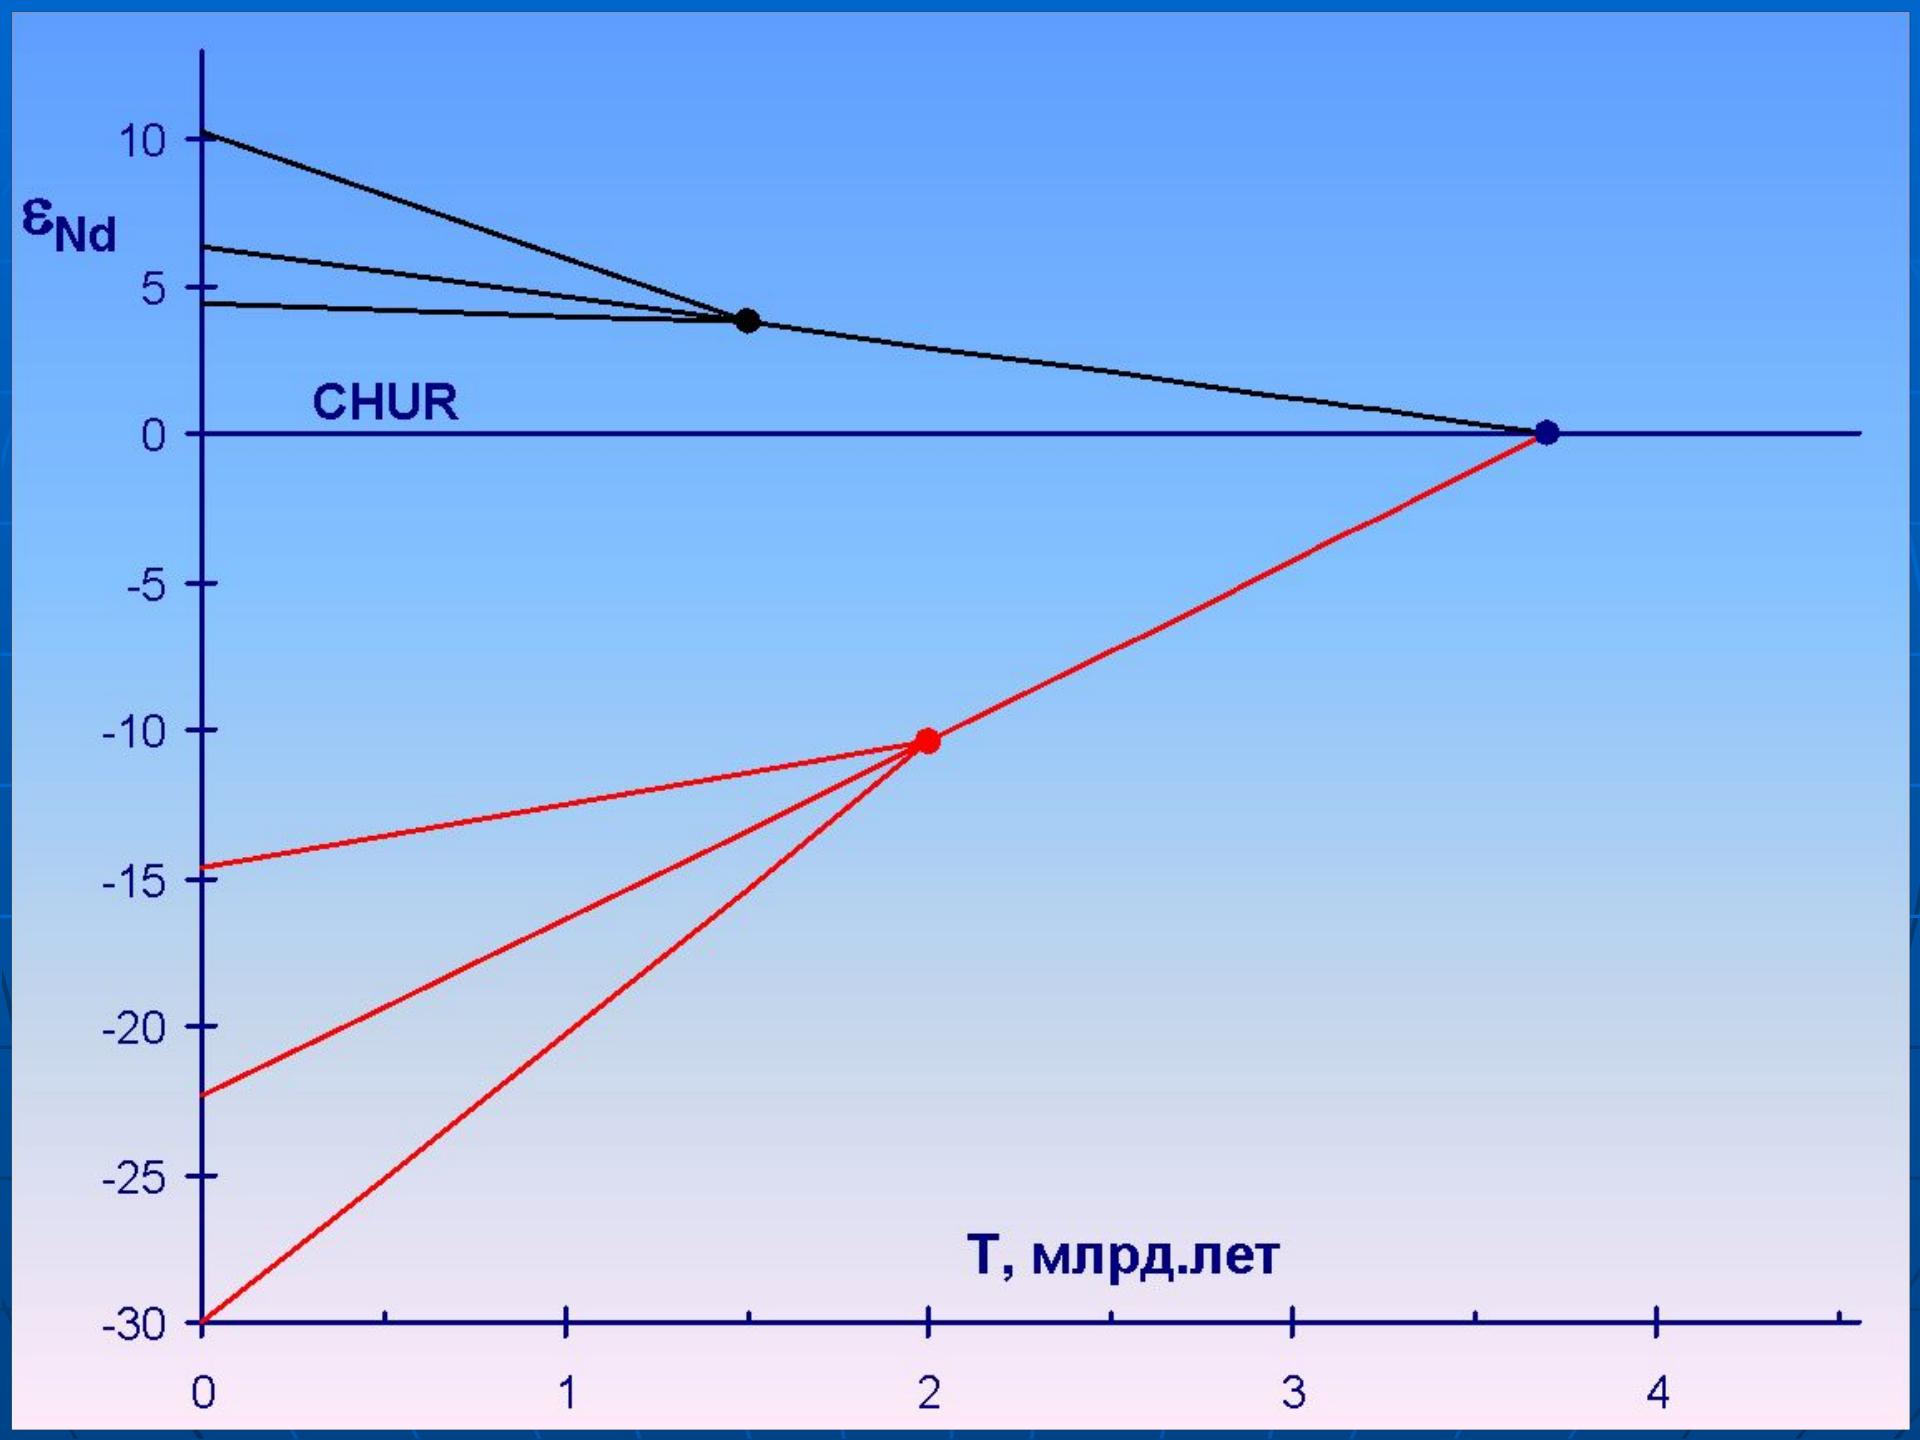

$\text{Rb/Sr} = 0.0286$

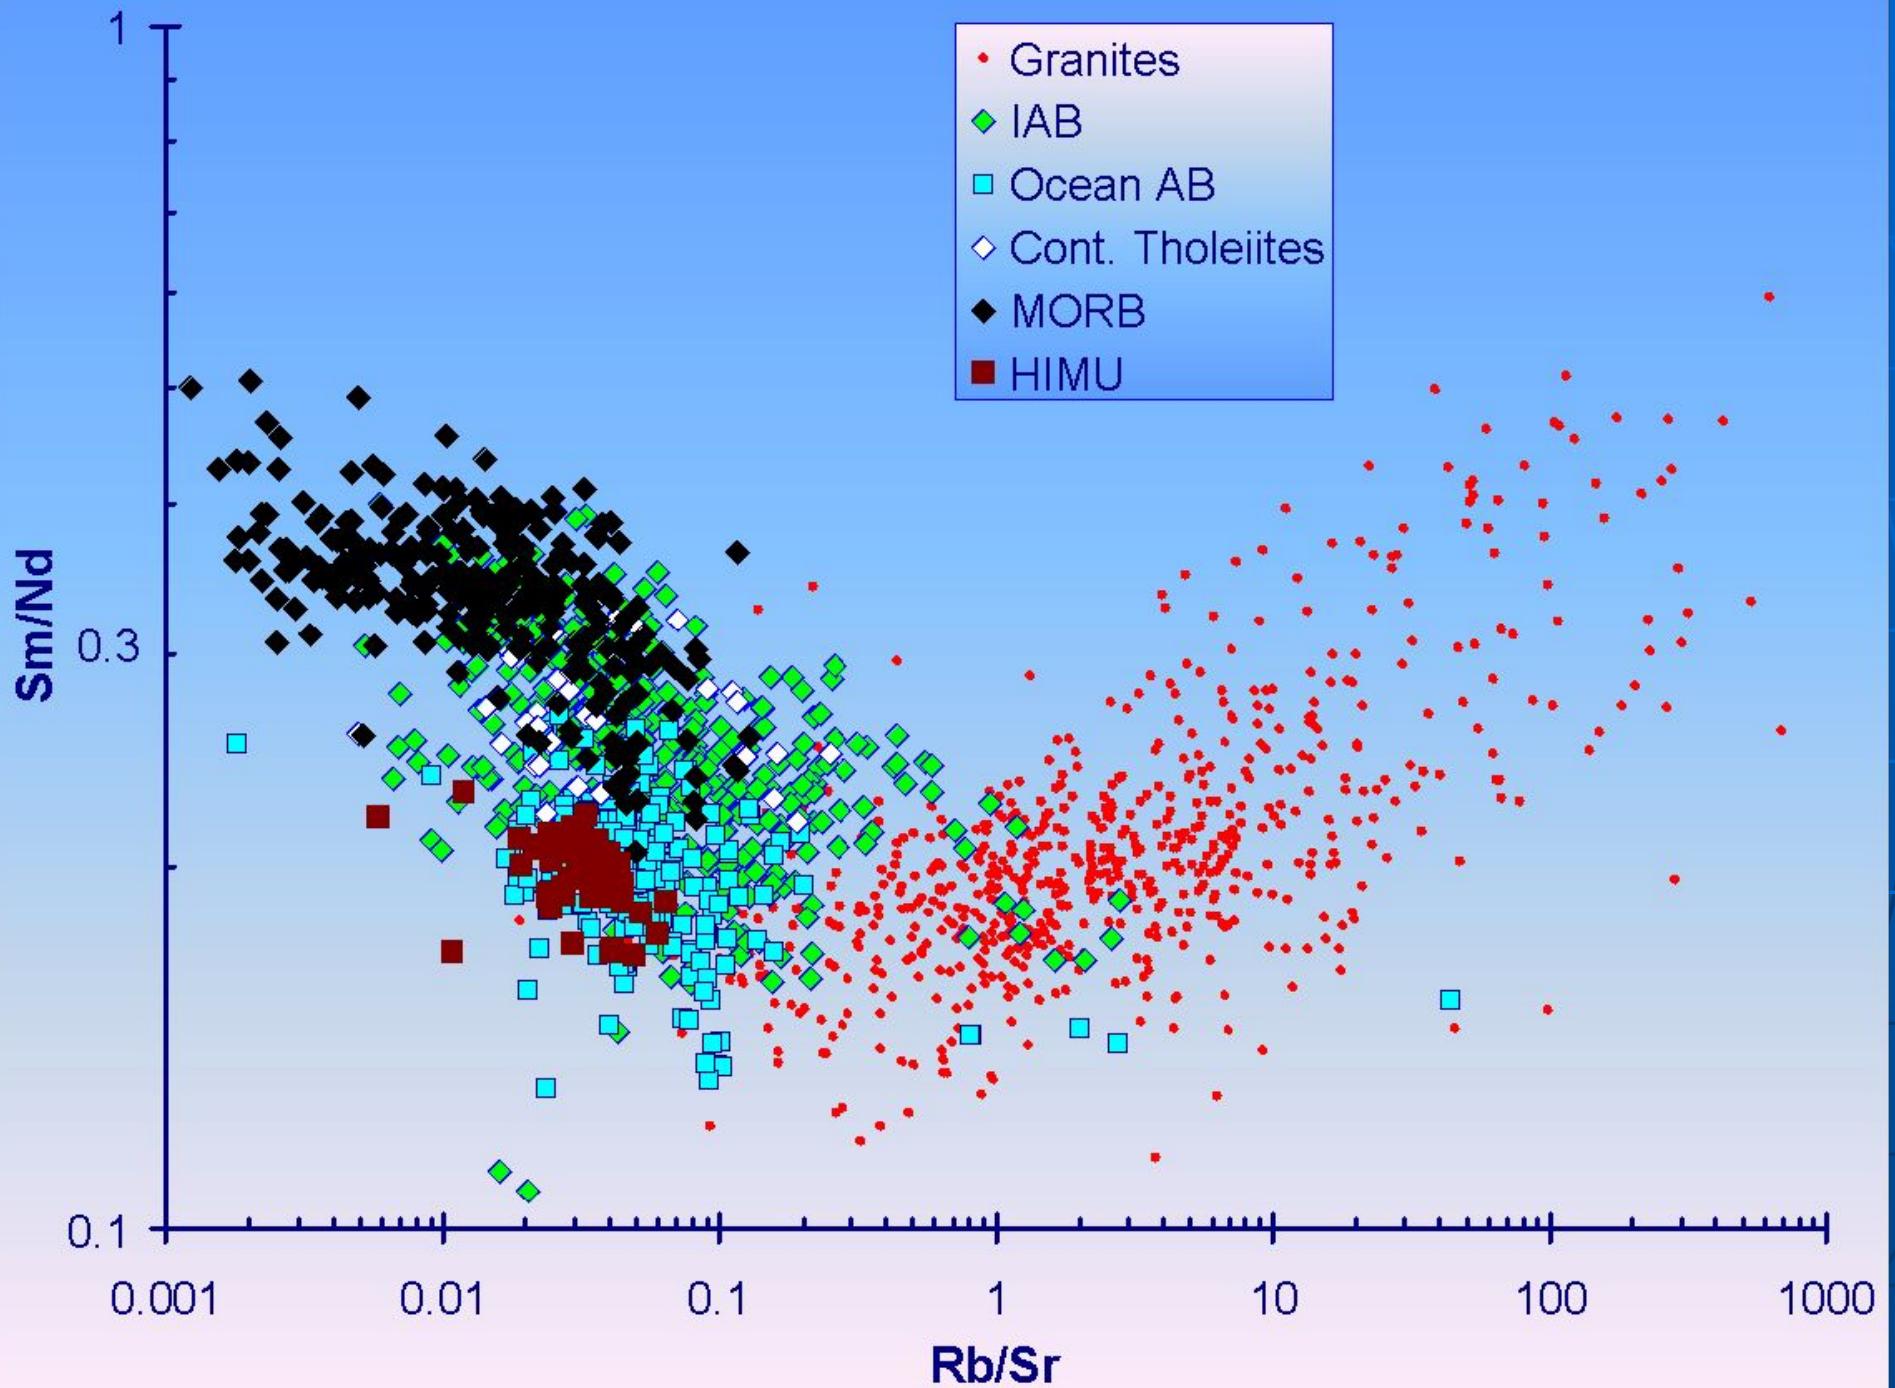

Fig. 4: ϵ_I^{CHUR} vs. initial $^{87}\text{Sr}/^{86}\text{Sr}$ for young basalts. Included are two samples from *Richard*, et. al. (1976) (PD1P, ARP74) and BCR-1 ($^{87}\text{Sr}/^{86}\text{Sr}$ for BCR-1 from *Pankhurst* and *O'Nions*, 1973). The solid line shows the inferred trend of the correlation and the relative magnitudes of correlated variations of Rb/Sr and Sm/Nd necessary to produce such a trend. The dashed line indicates the trend defined by four continental basalt samples which have $\epsilon_I^{\text{CHUR}} \approx 0$ but different $^{87}\text{Sr}/^{86}\text{Sr}$, all lying to the right of the main correlation line. This trend may result from contamination of magmas with crustal radiogenic Sr or indicate the existence of magma sources which have become enriched in Rb relative to Sr, but have retained unchanged Sm/Nd. Should new data populate the correlation line to values of ϵ_I^{CHUR} much less than zero, it would require serious revision of the simple two-reservoir model.

Проблема баланса кора-мантия

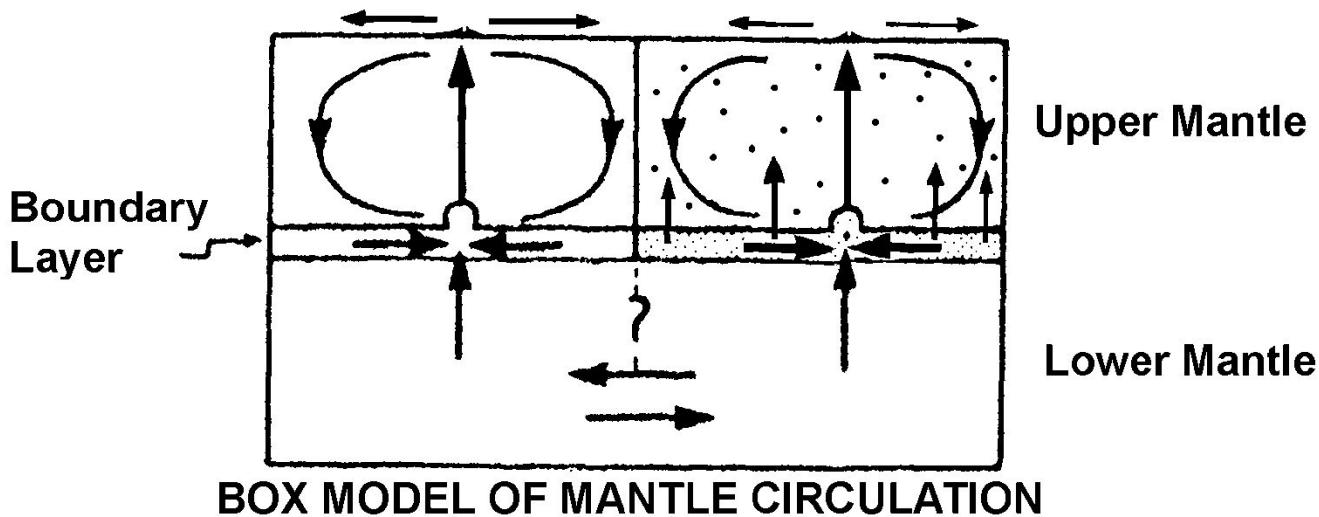

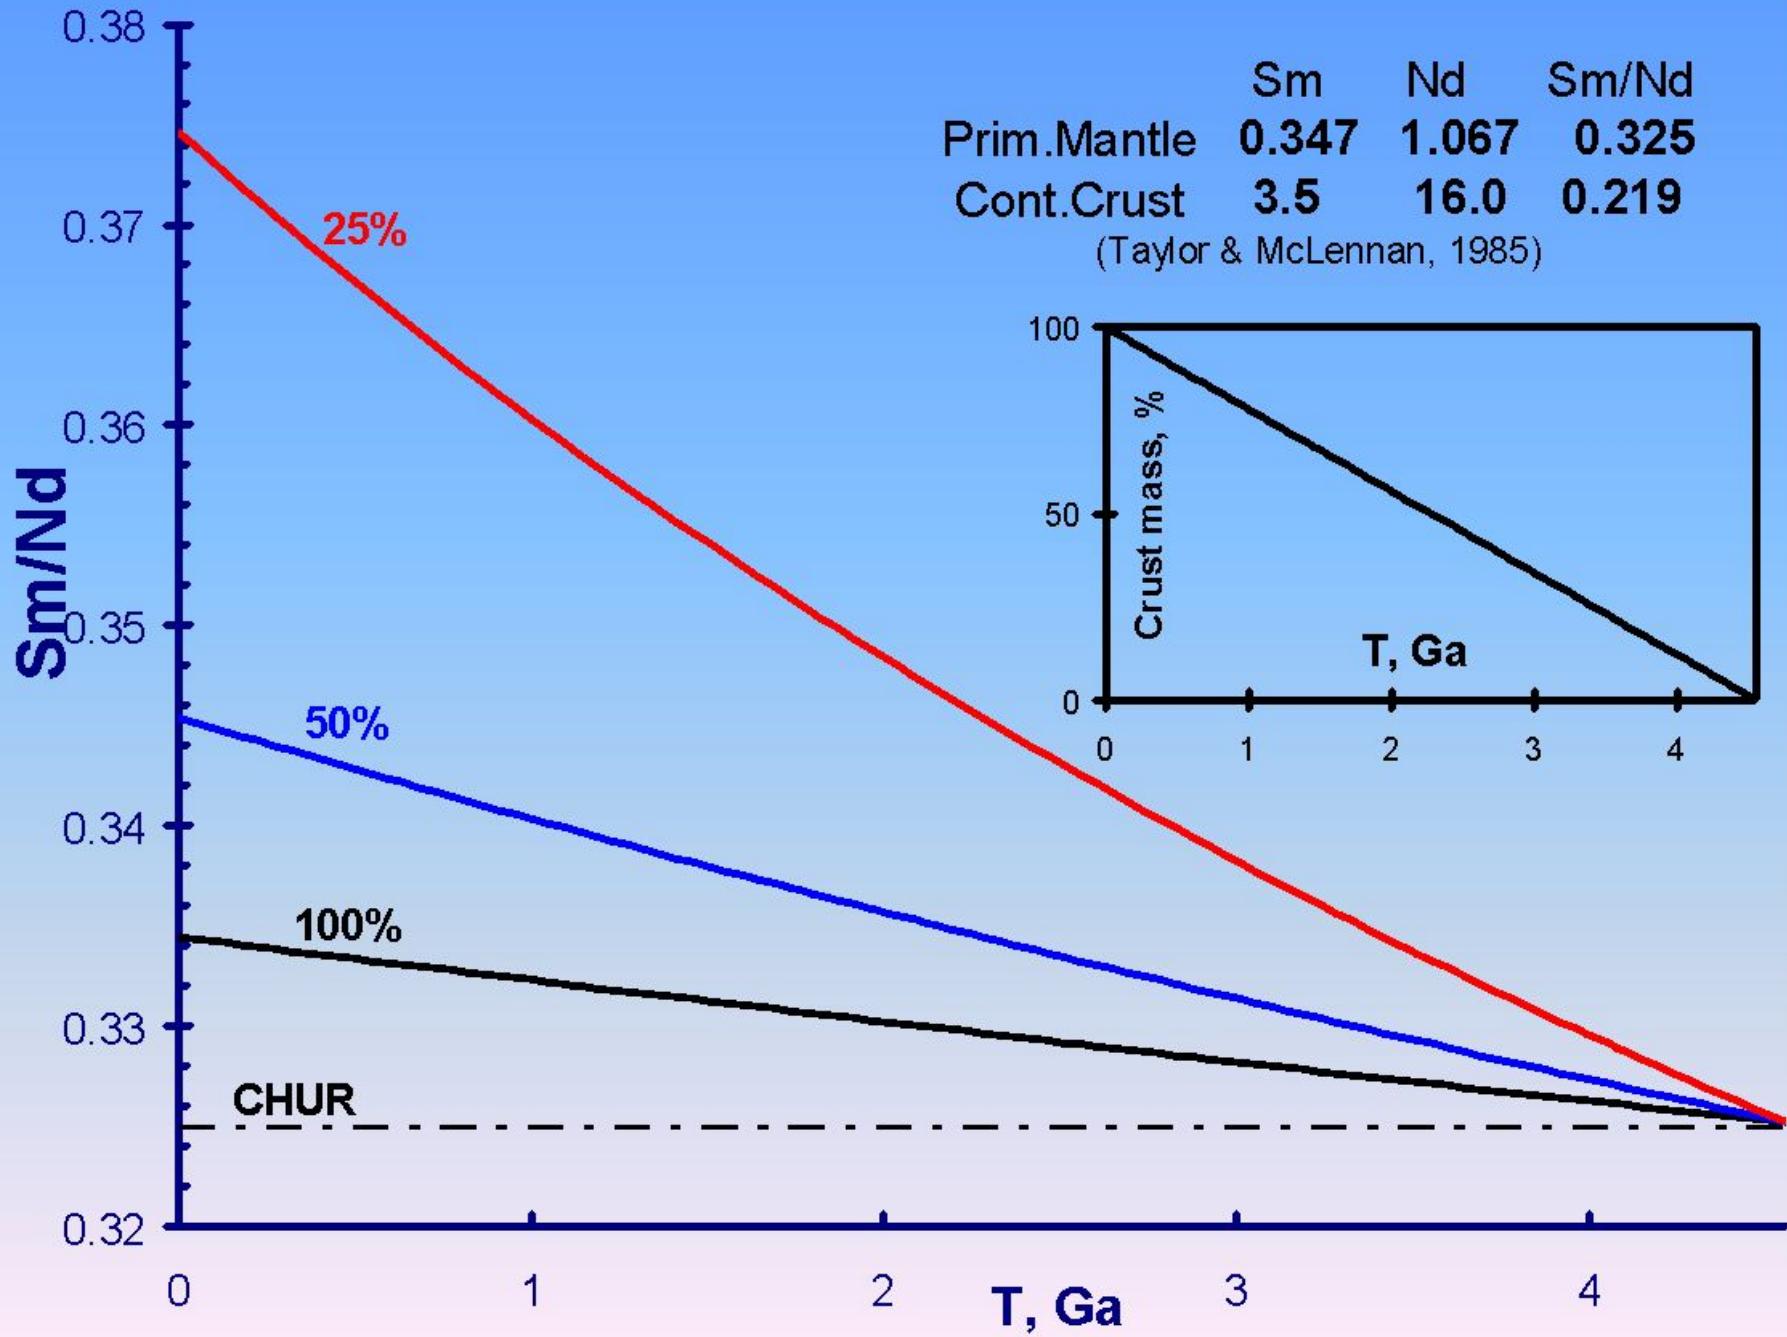

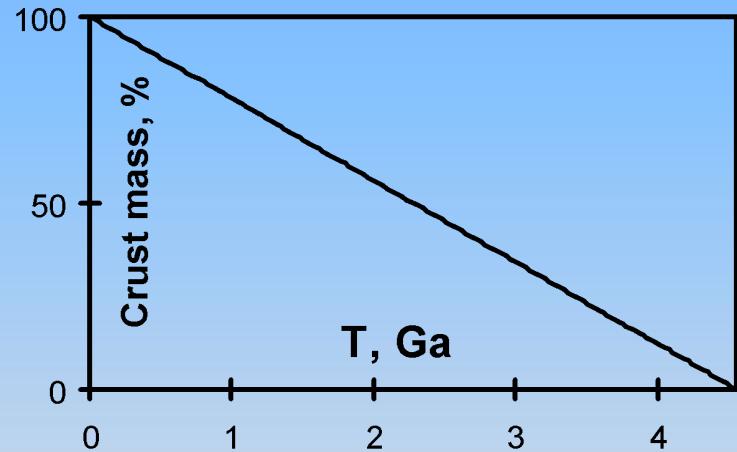

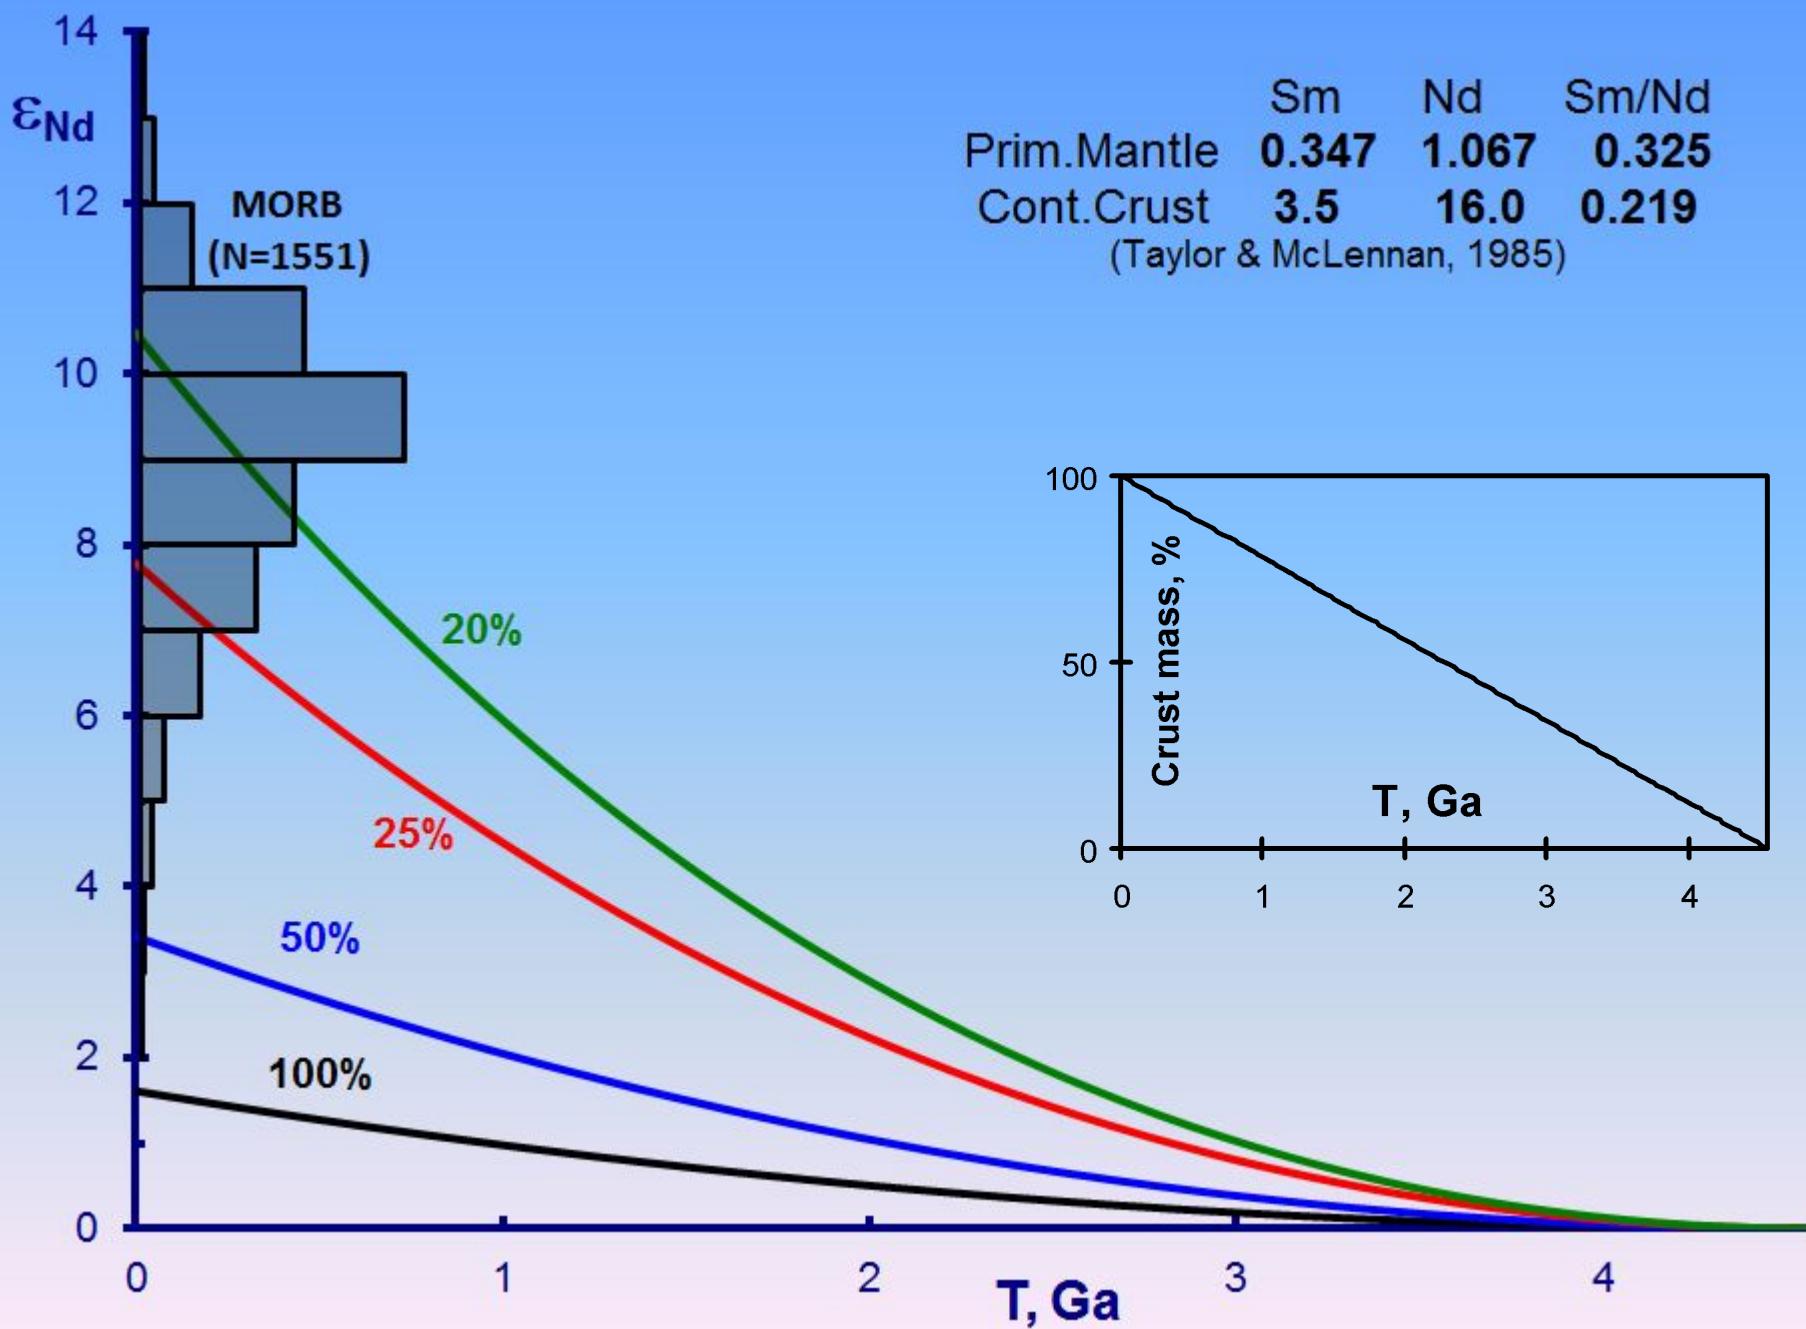

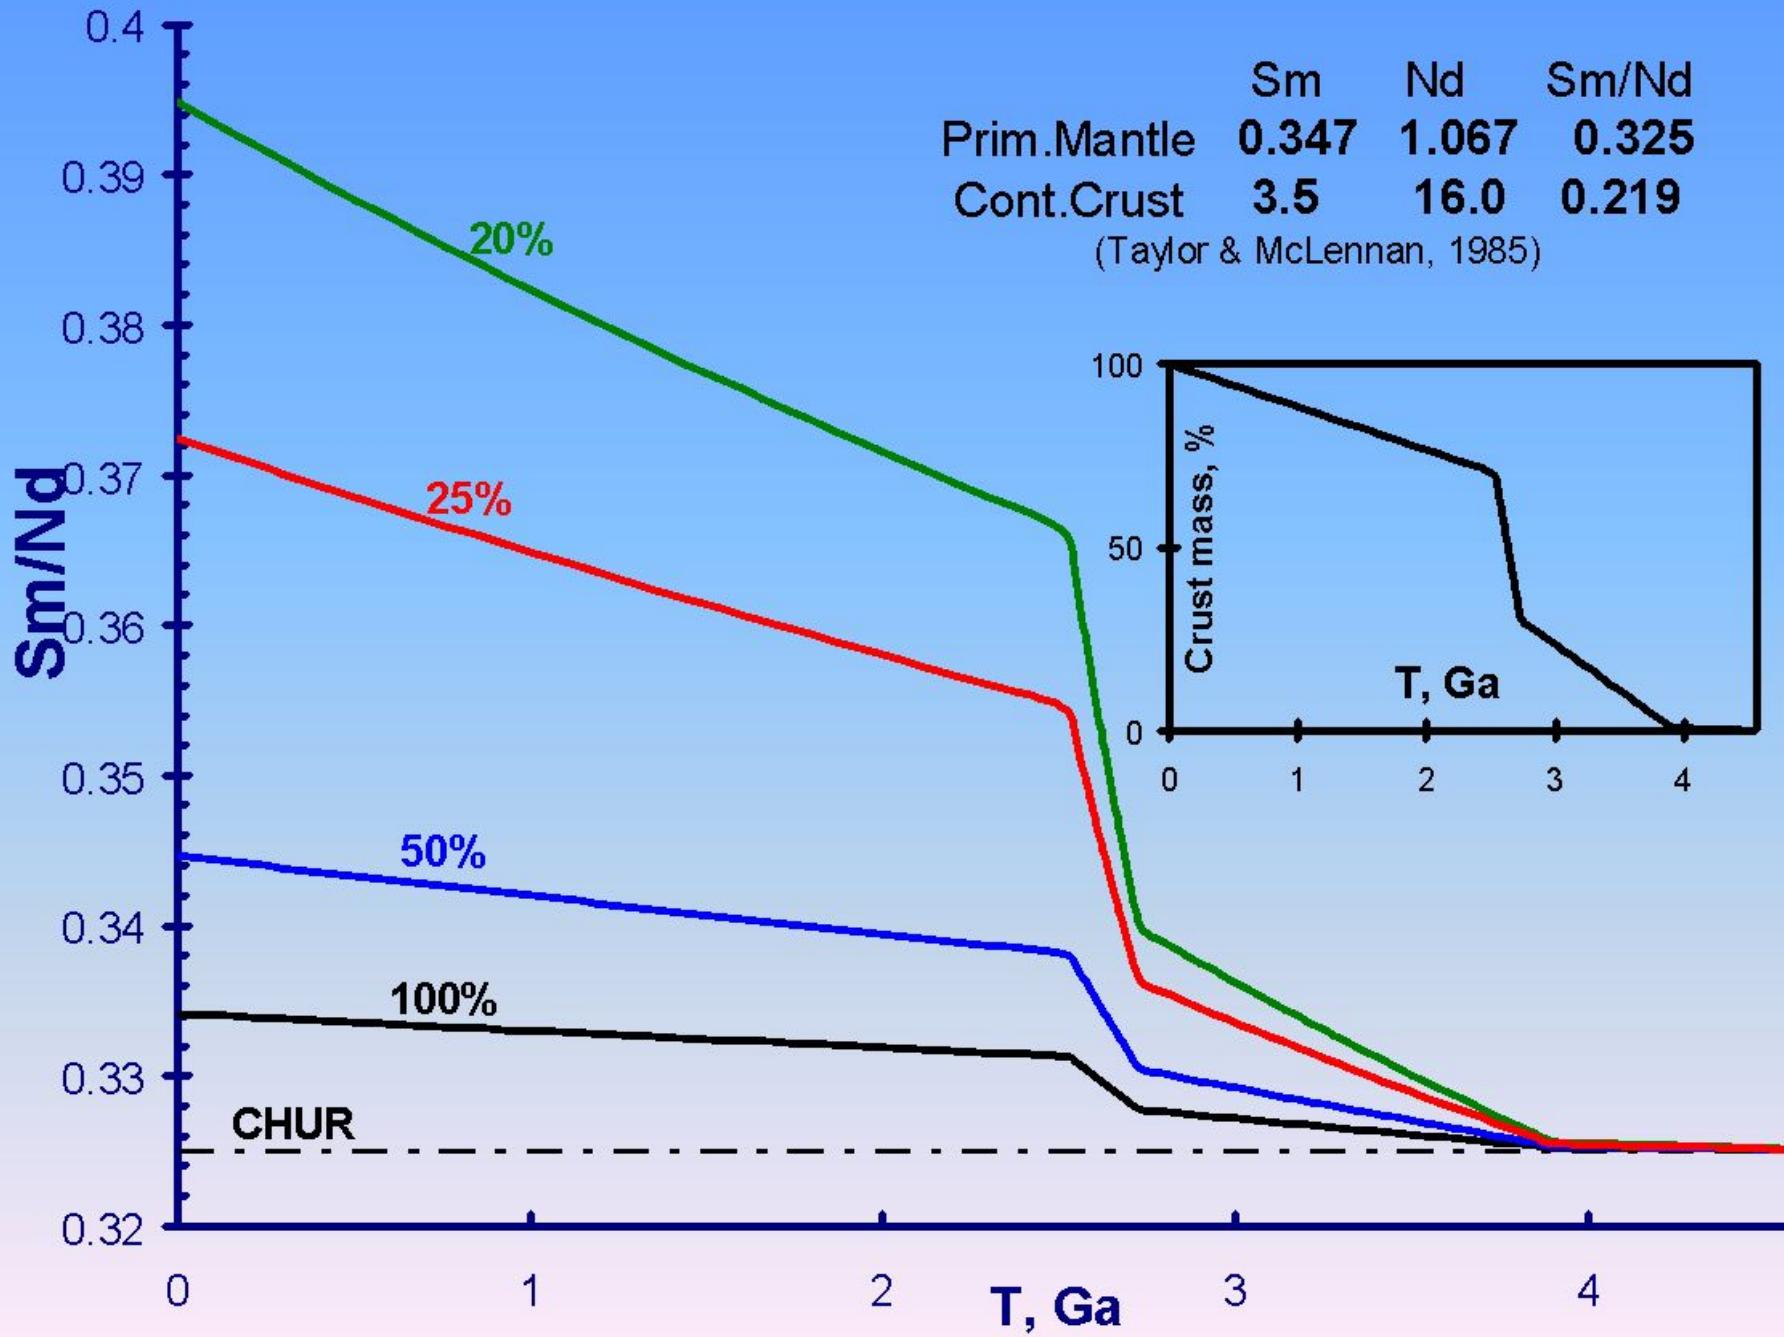

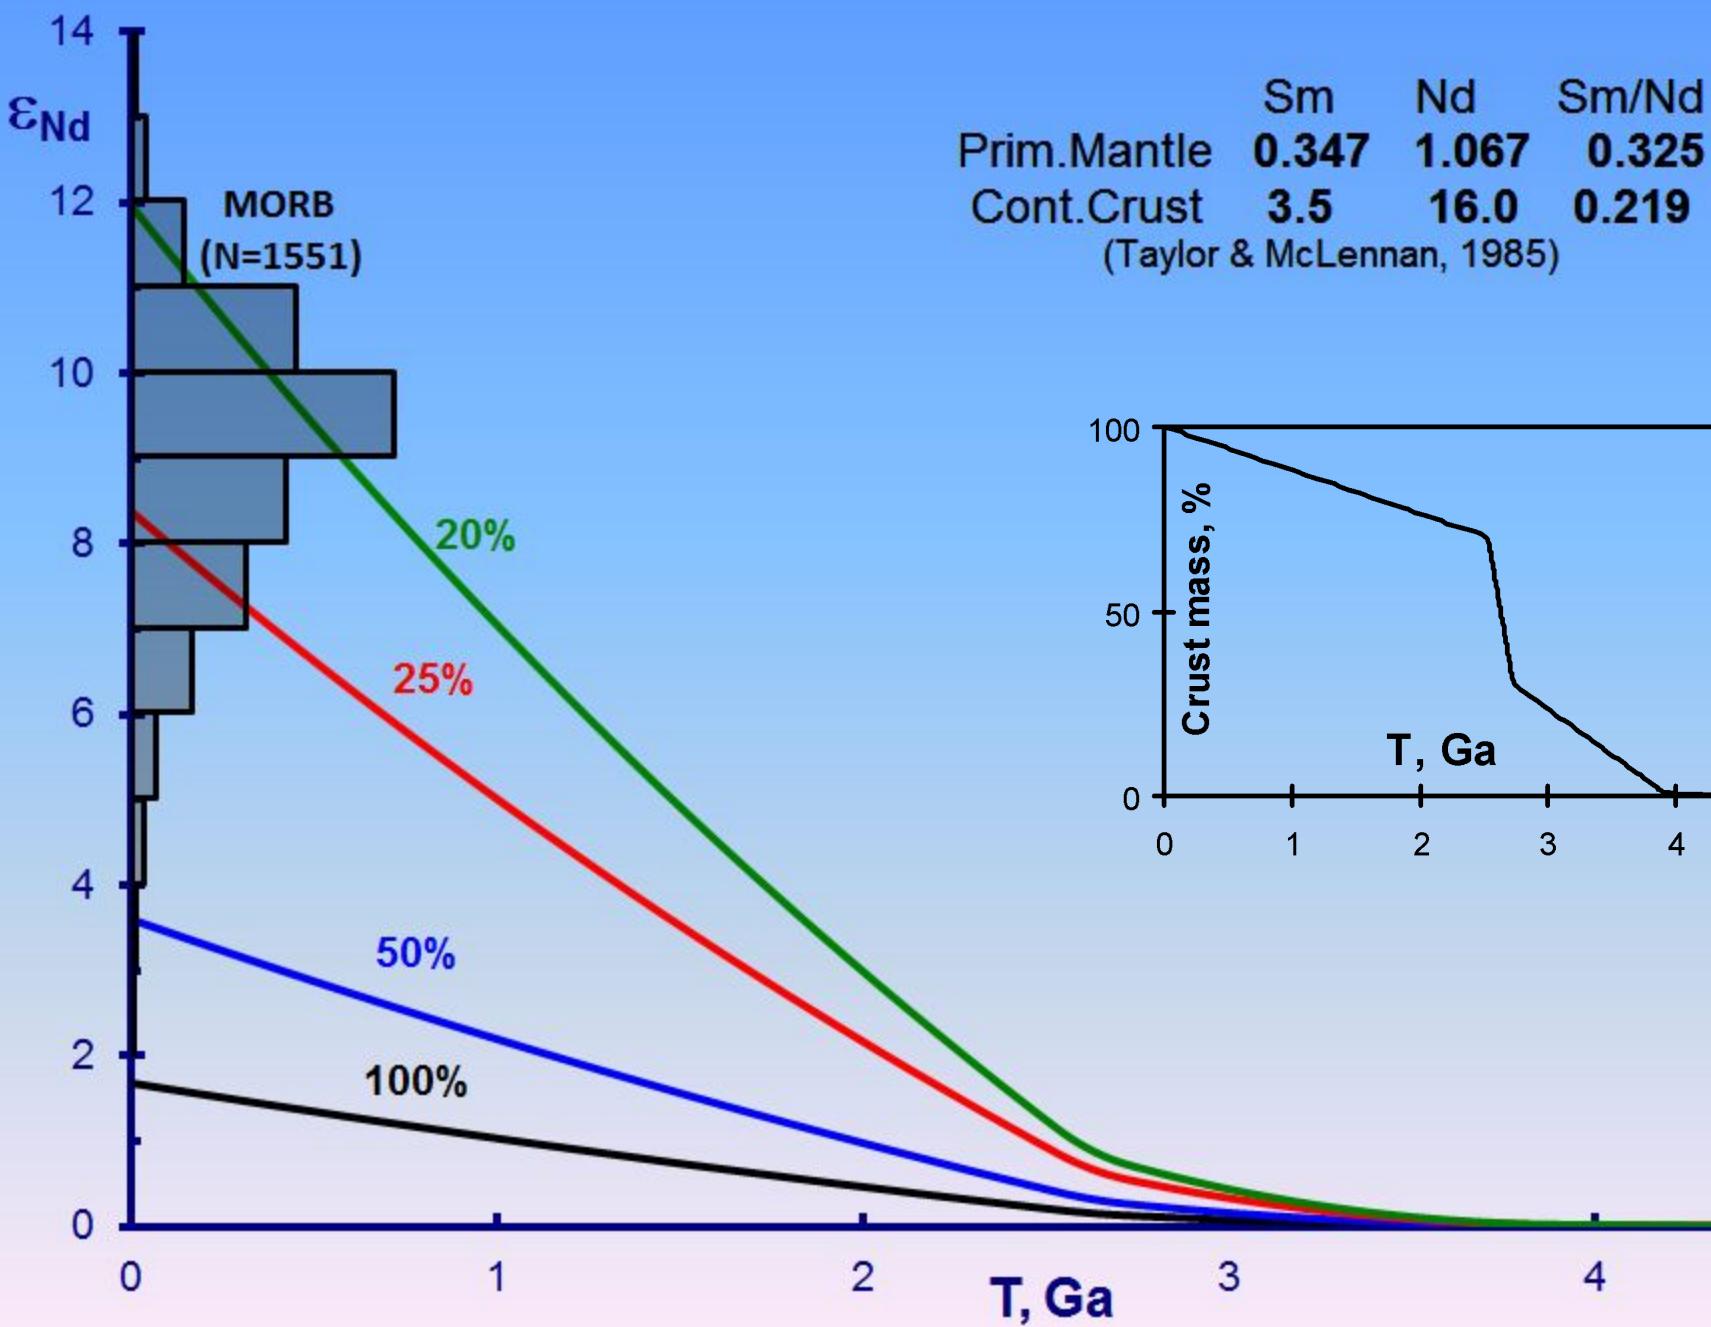

Fig. 5 Possible scheme of mantle dynamics. The upper mantle is divided in different discontinuous boxes, according to the SWIR MORB isotope results. The model where ocean island basalts originate in the boundary layer between upper and lower mantle³⁸ is illustrated as an example. Since the Indian Ocean island basalt source material (dotted area) is different from other parts of the world, the sub-Indian upper mantle is contaminated specifically by these Indian blobs, some of which reach the surface and others becoming progressively mixed within the upper mantle convection cell.

Smith A.D., Ludden J.N. Nd isotopic evolution of the Precambrian mantle. // Earth and Planetary Science Letters. 1989. 93: 14-22.

Partial melting

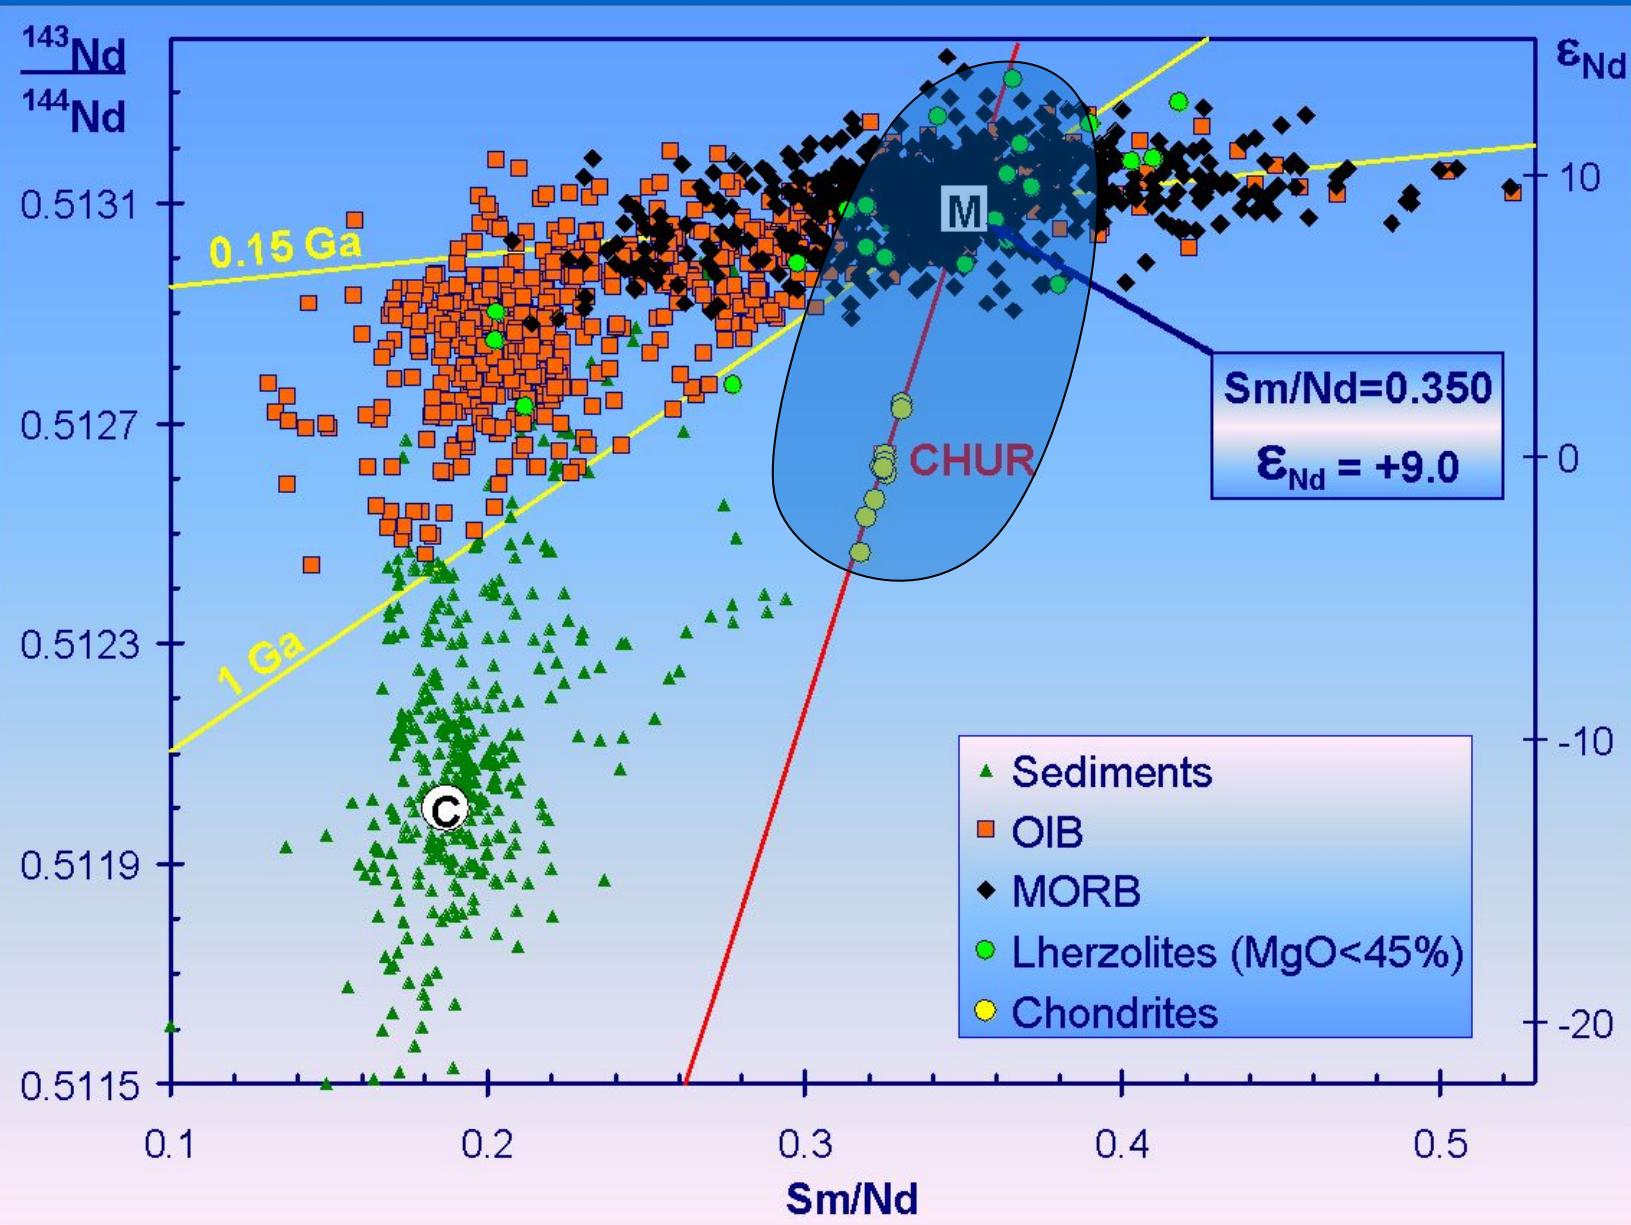

- Прямые выплавки (E) из примитивной мантии и рестит (D) должны иметь начальный изотопный состав этого источника и комплементарные отношения Sm/Nd
- Линии смешения обеднённого и обогащённого вещества в этих координатах – прямые, проходящие через исходный (примитивный) источник
- Прямые выплавки толеитов из CHUR должны иметь:

$$\begin{cases} \varepsilon_{\text{Nd}} \approx 0 \\ \text{Sm/Nd} \approx 0.325 \end{cases}$$

Альтернатива:

- Мантия Земли в целом имеет отличное от хондритов Sm/Nd отношение

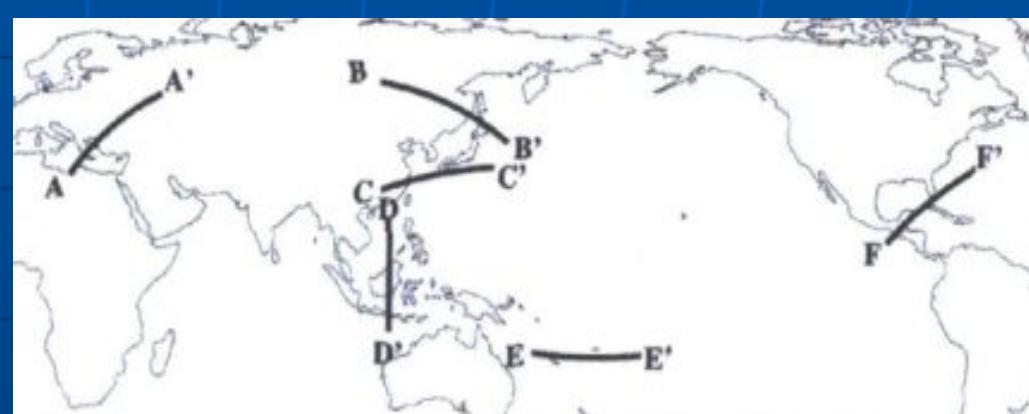

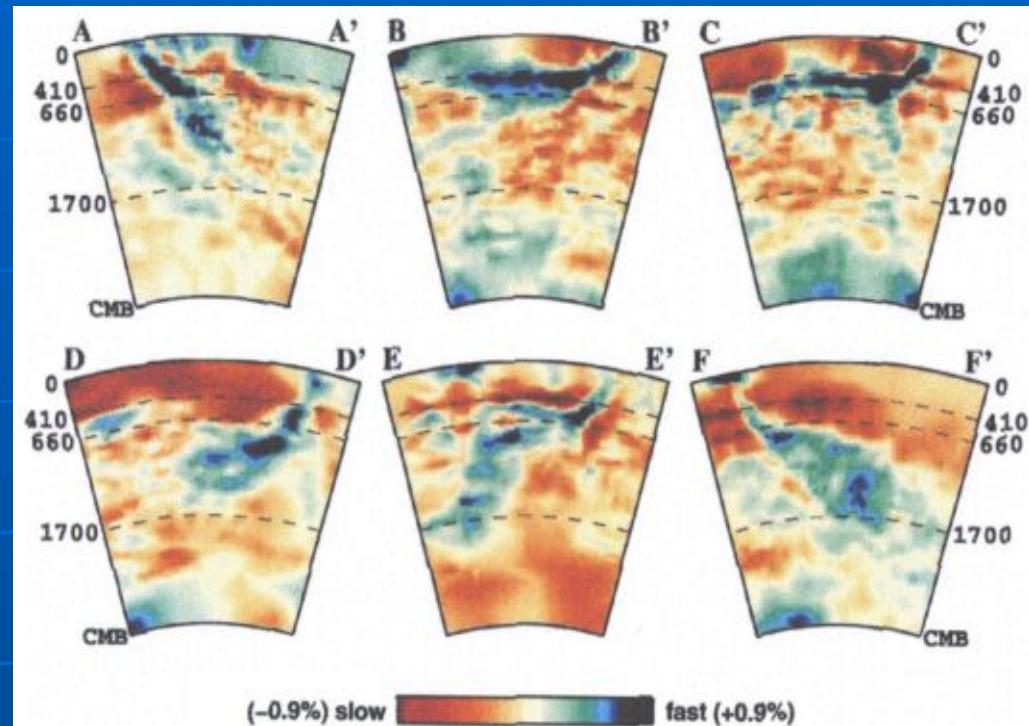

или

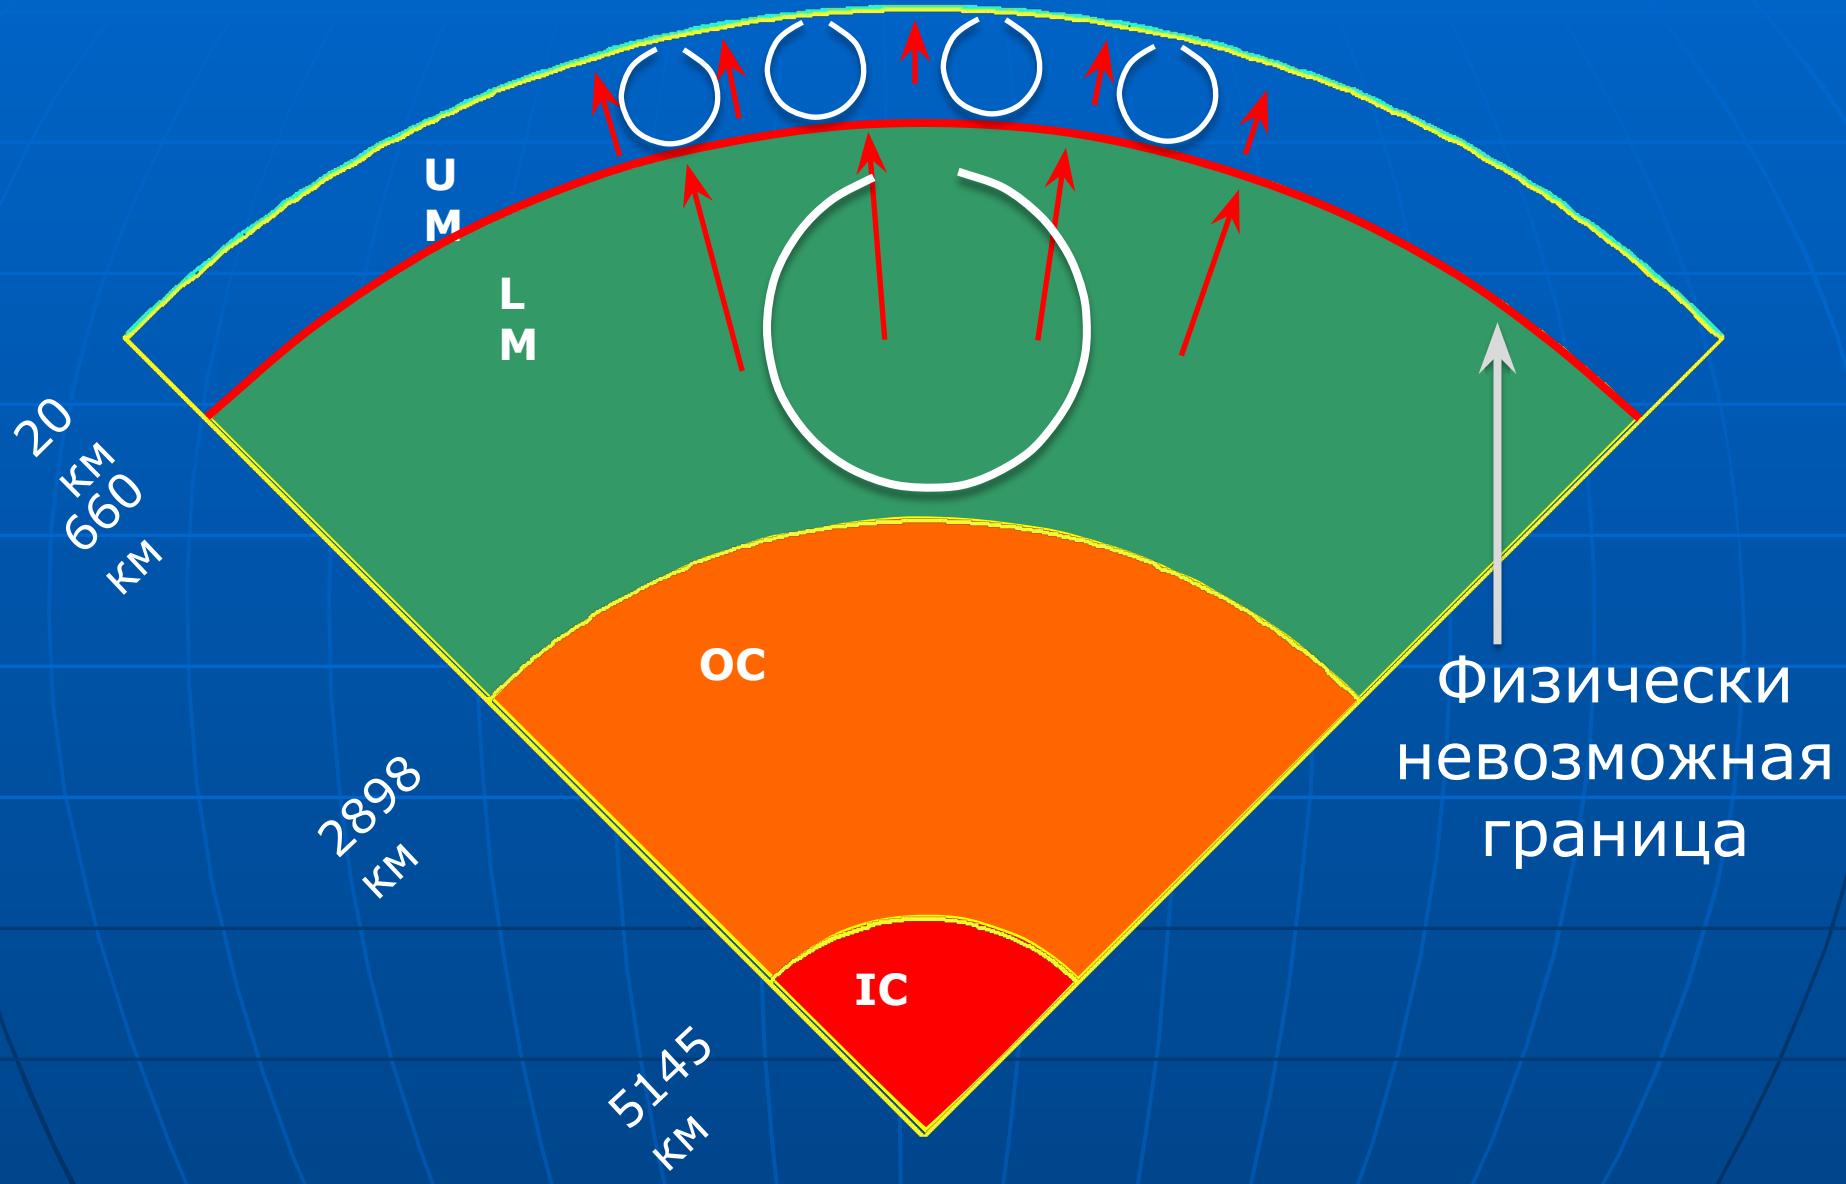

- Примитивное (необеднённое) вещество, в объёме нижней мантии, полностью изолировано на глубине

Поток вещества в нижнюю мантию фиксируется сейсмомографией.

Значит есть и обратный поток – из нижней мантии к поверхности Земли

D.C.Rubie, R.D. van der Hilst,
Physics of the Earth and Planetary Interiors.
2001. V.127. P. 1-7.

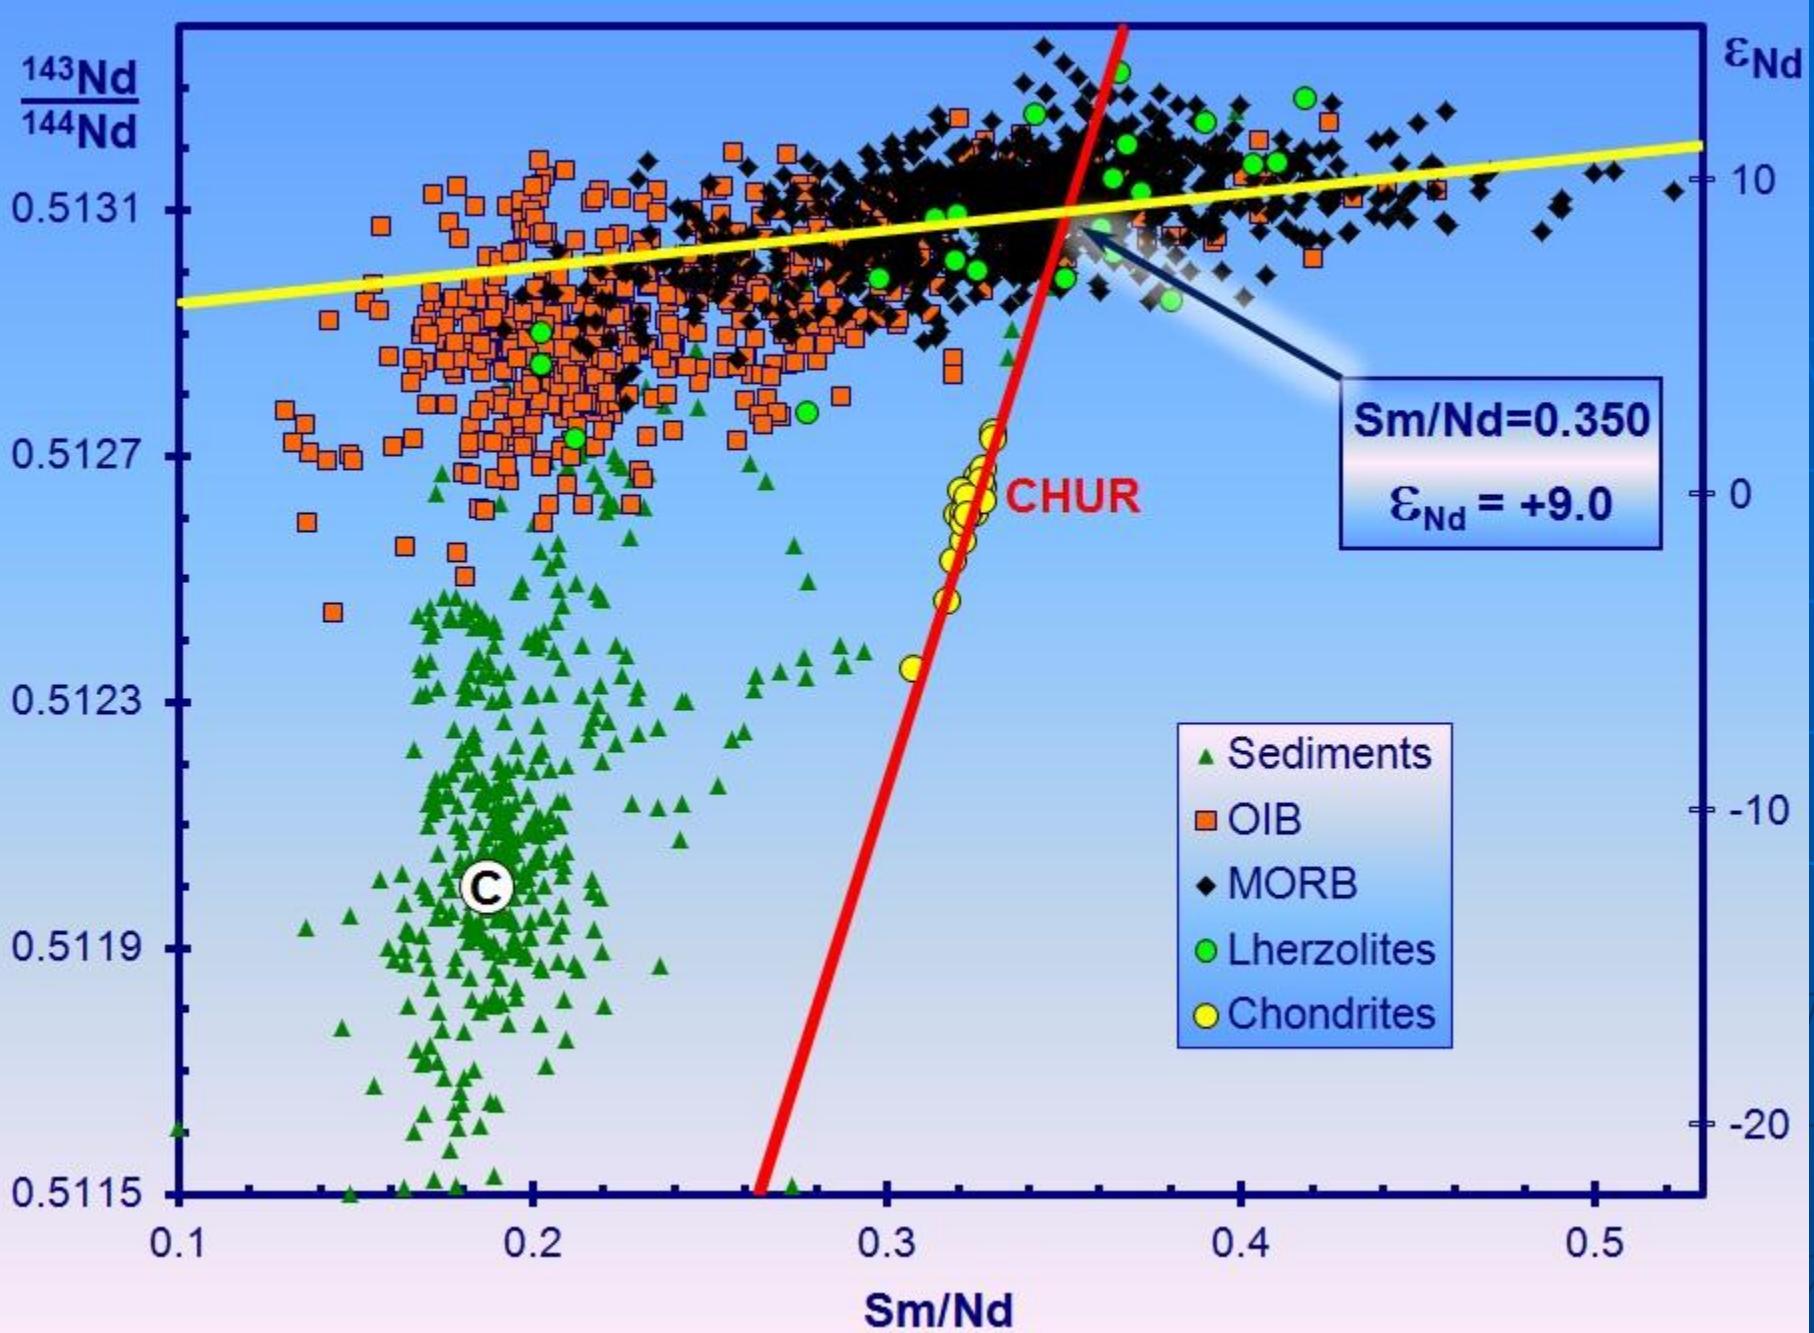

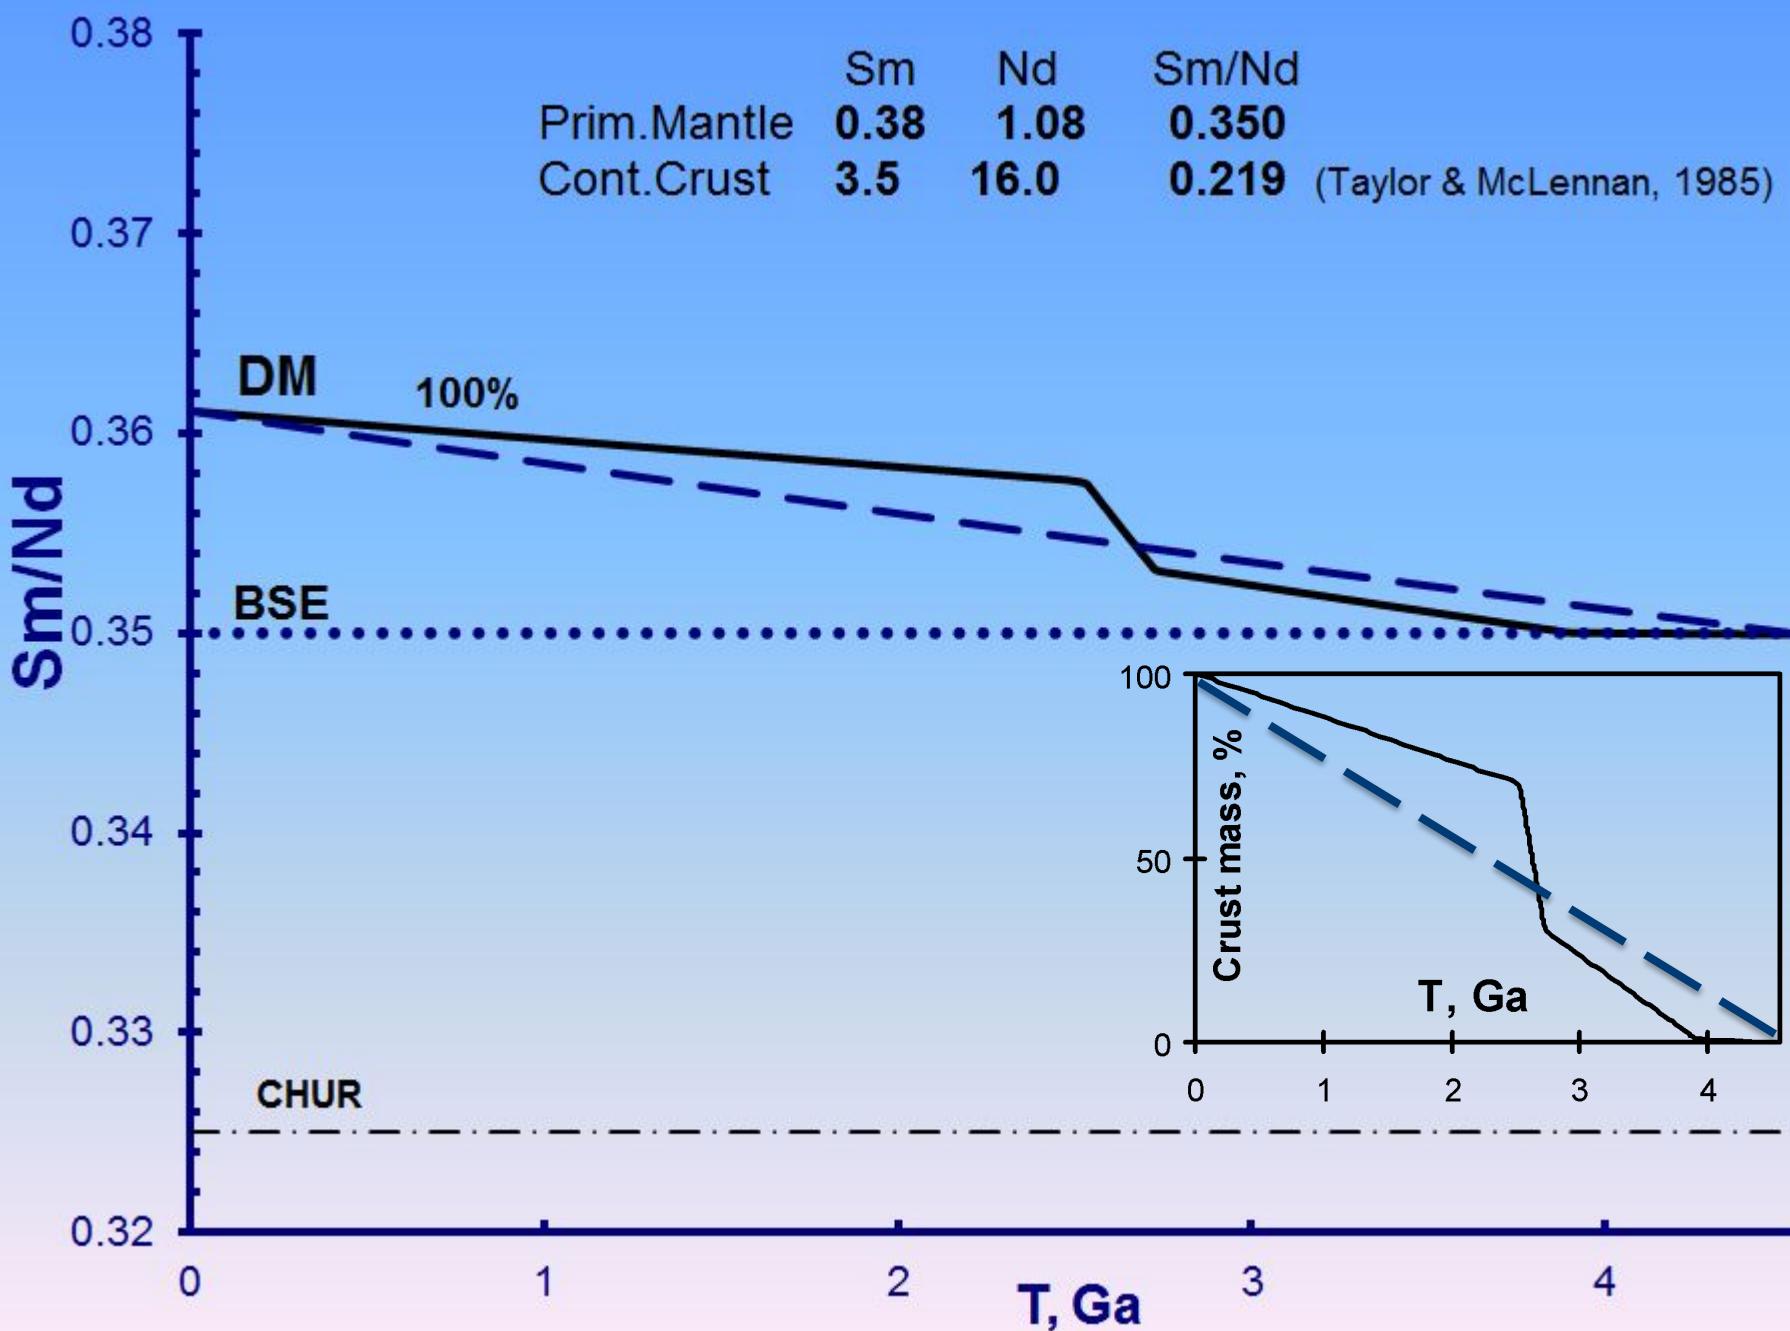

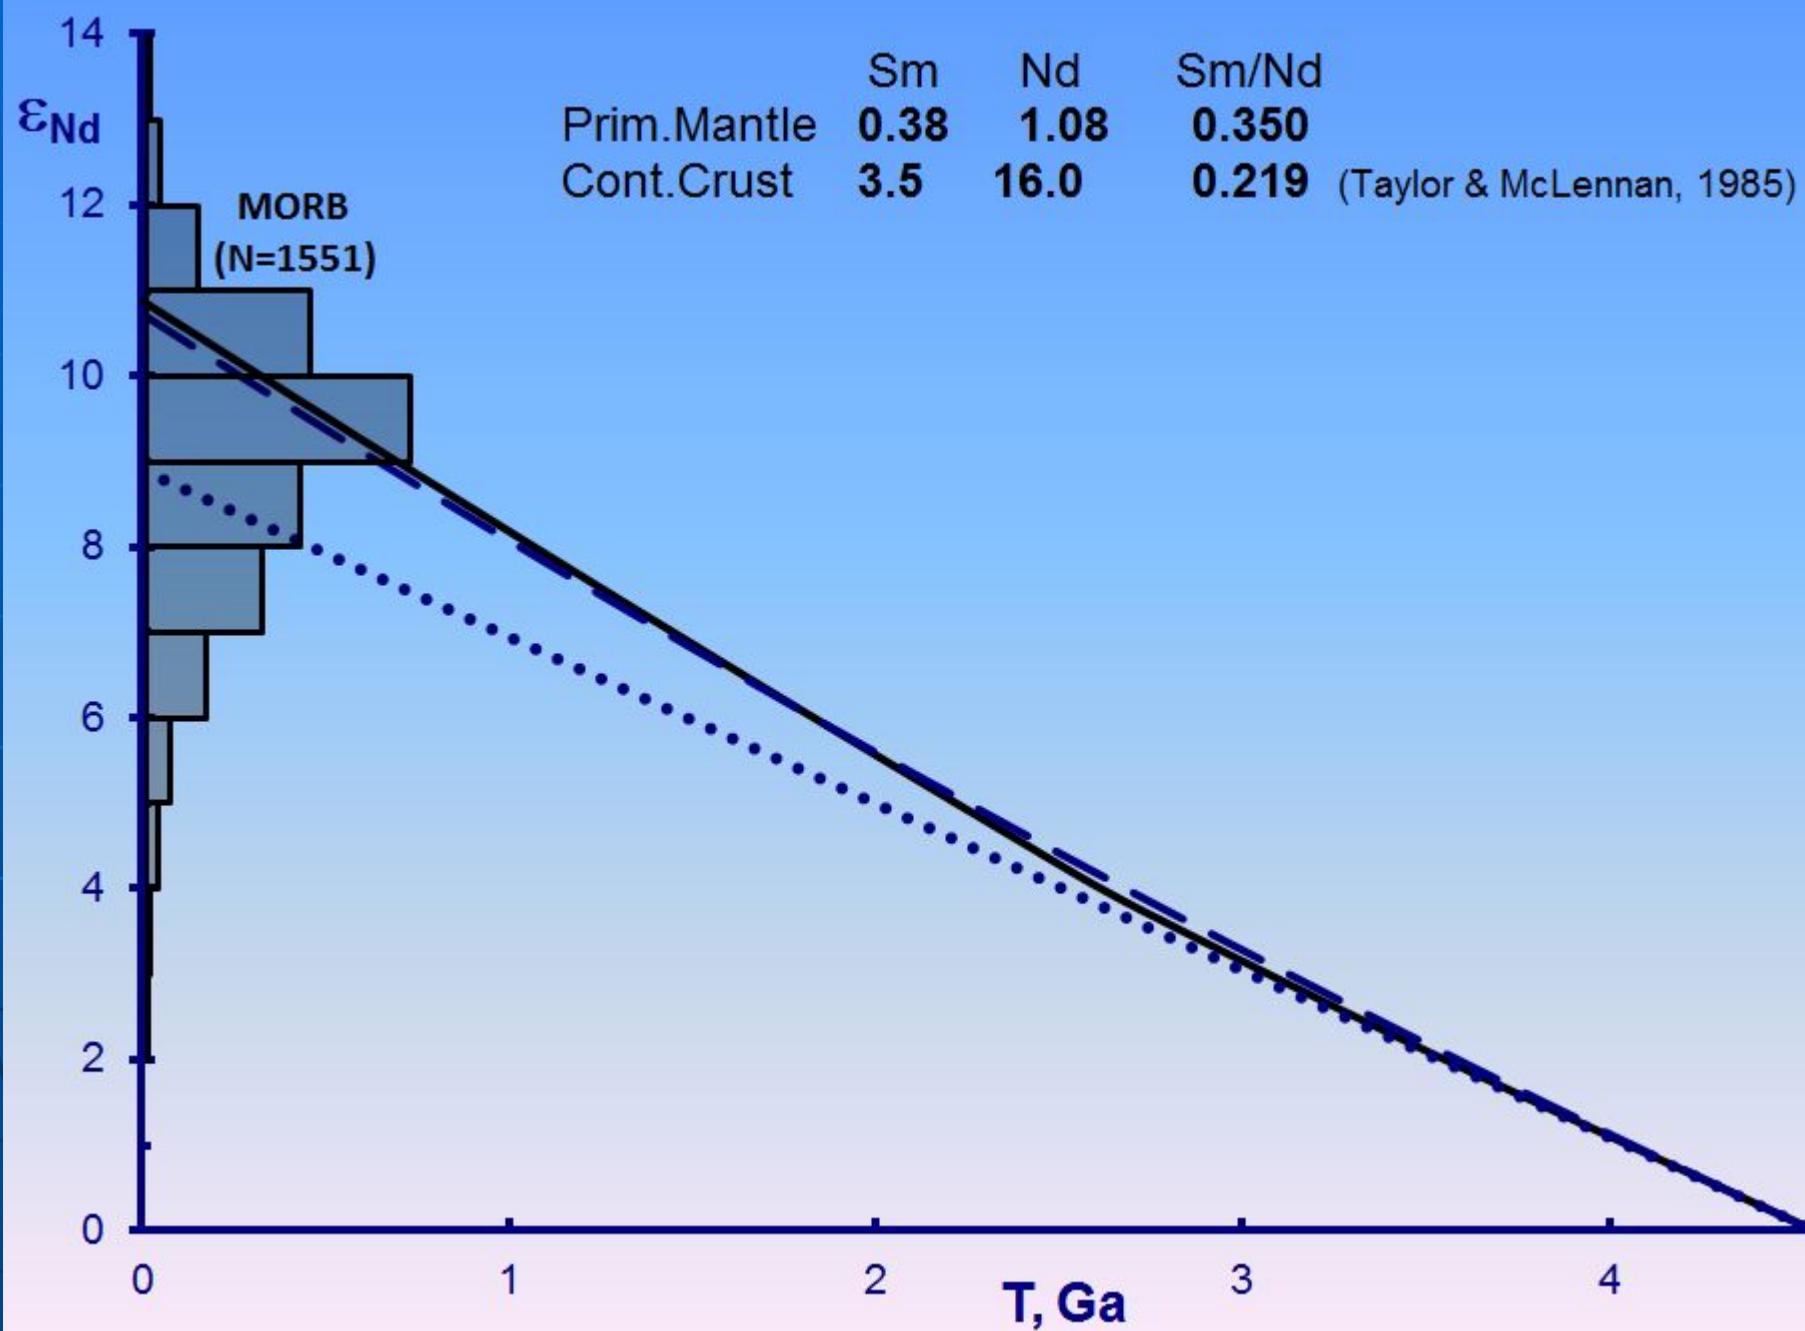

Вывод:

- Мантия Земли имеет отличное от хондритов Sm/Nd отношение

Какое?

Задача 14

- Рассчитать изотопный состав обеднённой мантии (DM) при следующих допущениях:
 - DM образовалась в результате отделения вещества континентальной коры от примитивной мантии (а) хондритового и (б) нехондритового состава
 - средний возраст коры – по вариантам (файл Ex14.xlsx)
- Рассмотреть два случая:
 - 1) источник коры – вся мантия
 - 2) источник коры – верхняя мантия
- Сформулировать выводы ...

	Примитивная мантия		Конт. кора	DM	
	Хондритовая (CHUR/UR)	Нехондритовая		(а)	(б)
Rb, ppm	0.55	0.34	32		
Sr, ppm	19.25	17.2	260		
$^{87}\text{Rb}/^{86}\text{Sr}$	0.0827	0.0574			
$^{87}\text{Sr}/^{86}\text{Sr}$	0.7045	0.7028			
ε_{Sr}	0.0	-24		?	?
Sm, ppm	0.347	0.38	3.5		
Nd, ppm	1.067	1.08	16		
$^{147}\text{Sm}/^{144}\text{Nd}$	0.1967	0.2119			
$^{143}\text{Nd}/^{144}\text{Nd}$	0.512638	0.513099			
ε_{Nd}	0.0	9		?	?

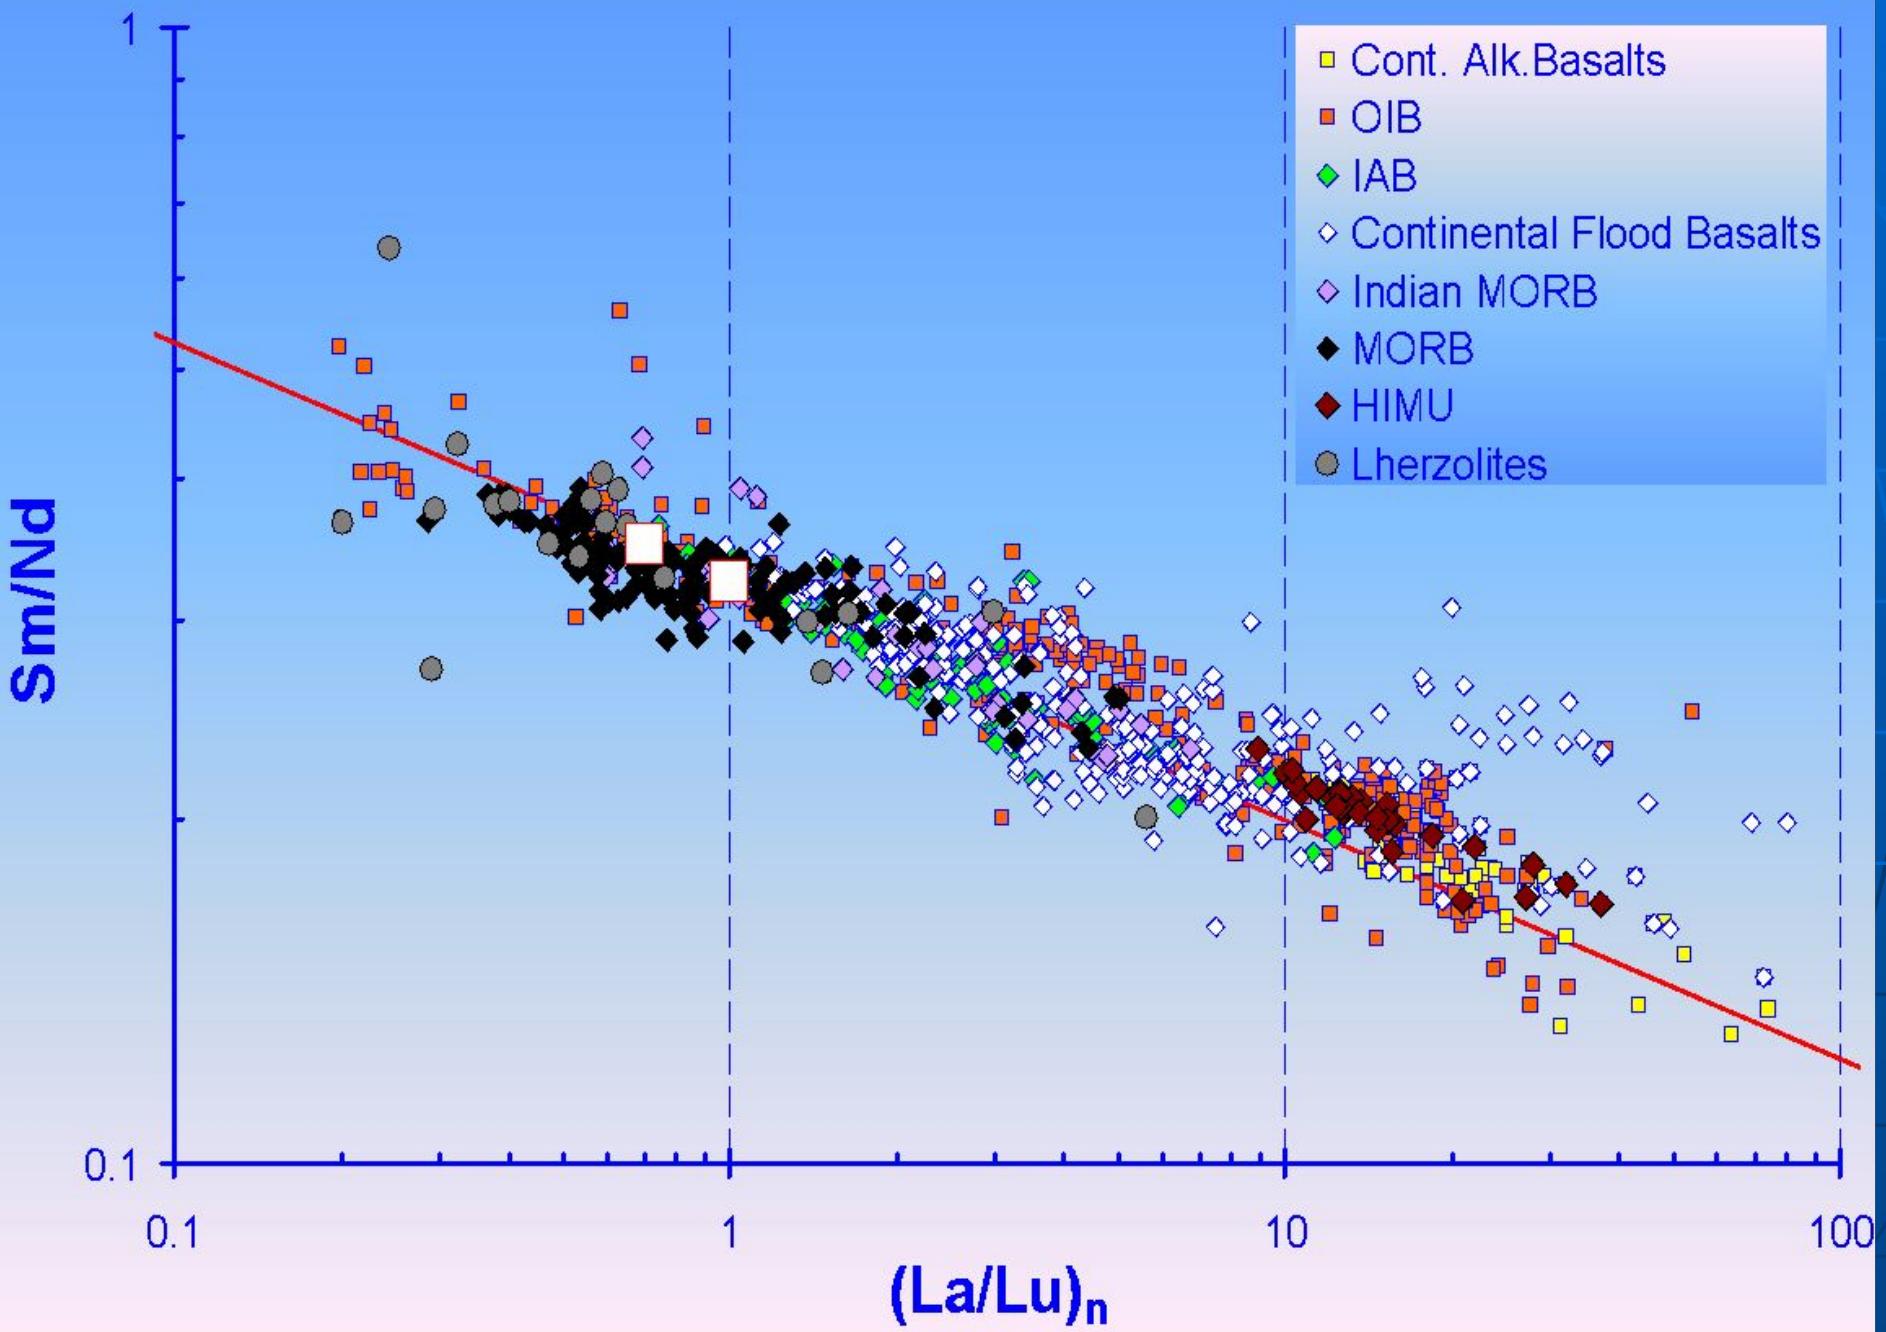

Состав примитивной мантии

- $\text{Sm}/\text{Nd} = 0.350$ и $^{143}\text{Nd}/^{144}\text{Nd} = 0.51310 \quad \varepsilon_{\text{Nd}} = 9$
→
- $\text{Rb/Sr} = 0.020 \quad \rightarrow \quad ^{87}\text{Sr}/^{86}\text{Sr} = 0.7028 \quad \varepsilon_{\text{Sr}} = -24$
 $(^{87}\text{Sr}/^{86}\text{Sr})_{\text{BABI}} = 0.699$

$$\lambda = 6.74 \times 10^{-9} \text{ год}^{-1}$$

$$T_{1/2} = 103 \text{ млн. лет}$$

$$N_0 = N \exp(\lambda t)$$

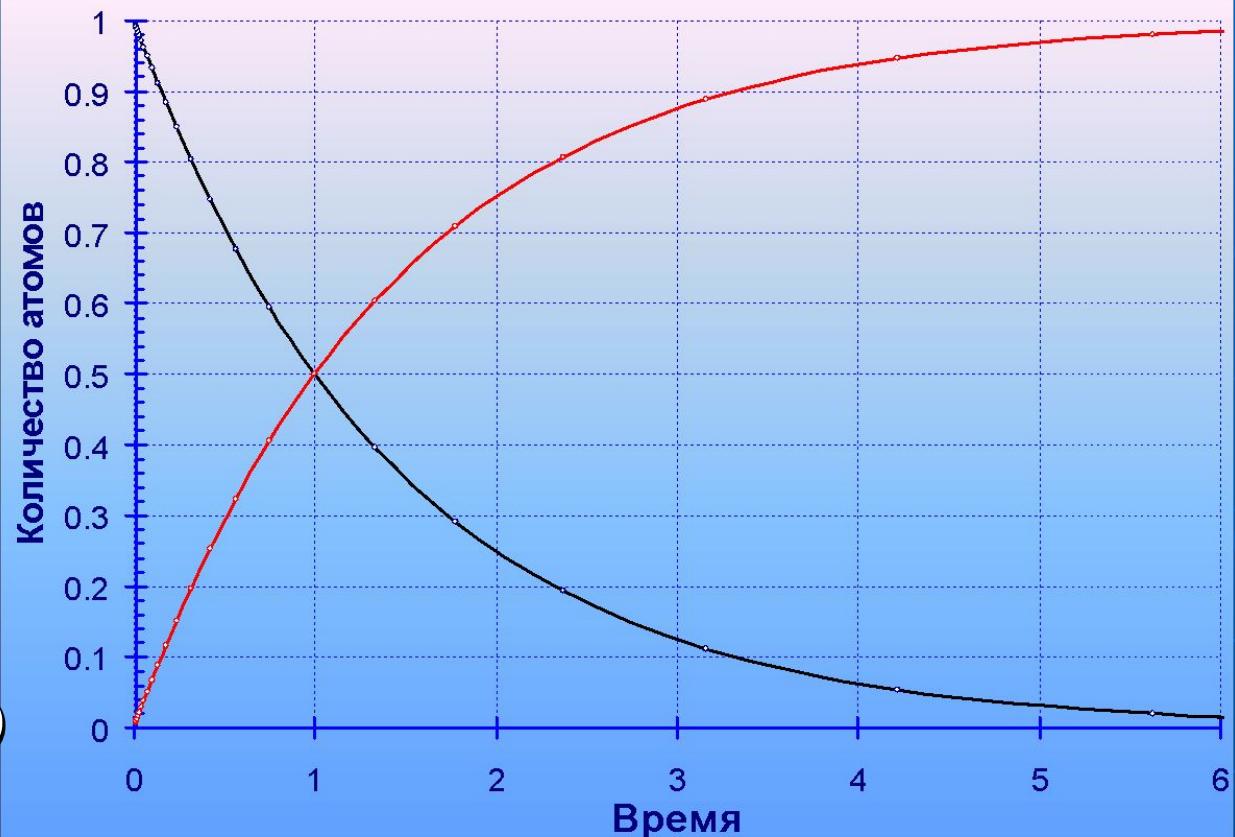

$$N = N_0 \exp(-\lambda t)$$

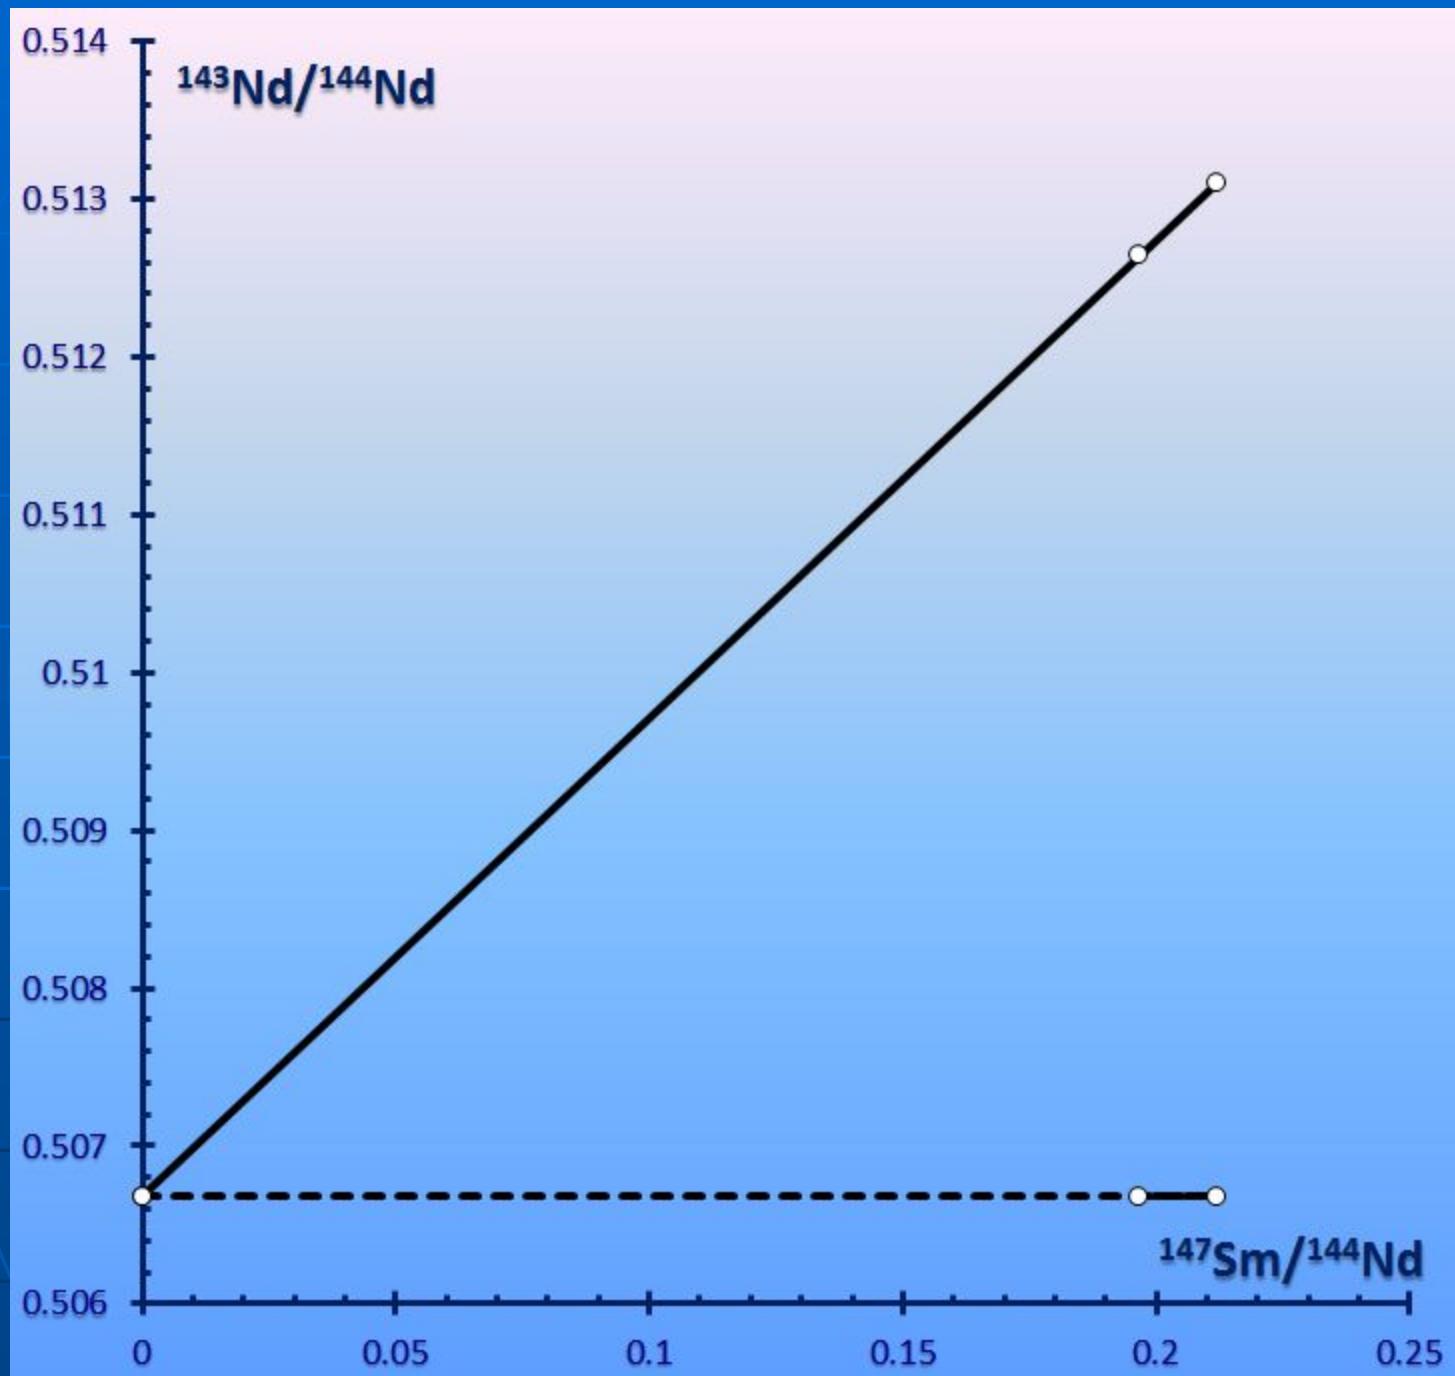

$$^{146}\text{Sm} = ^{146}\text{Sm}_0 \cdot \exp(-\lambda t)$$

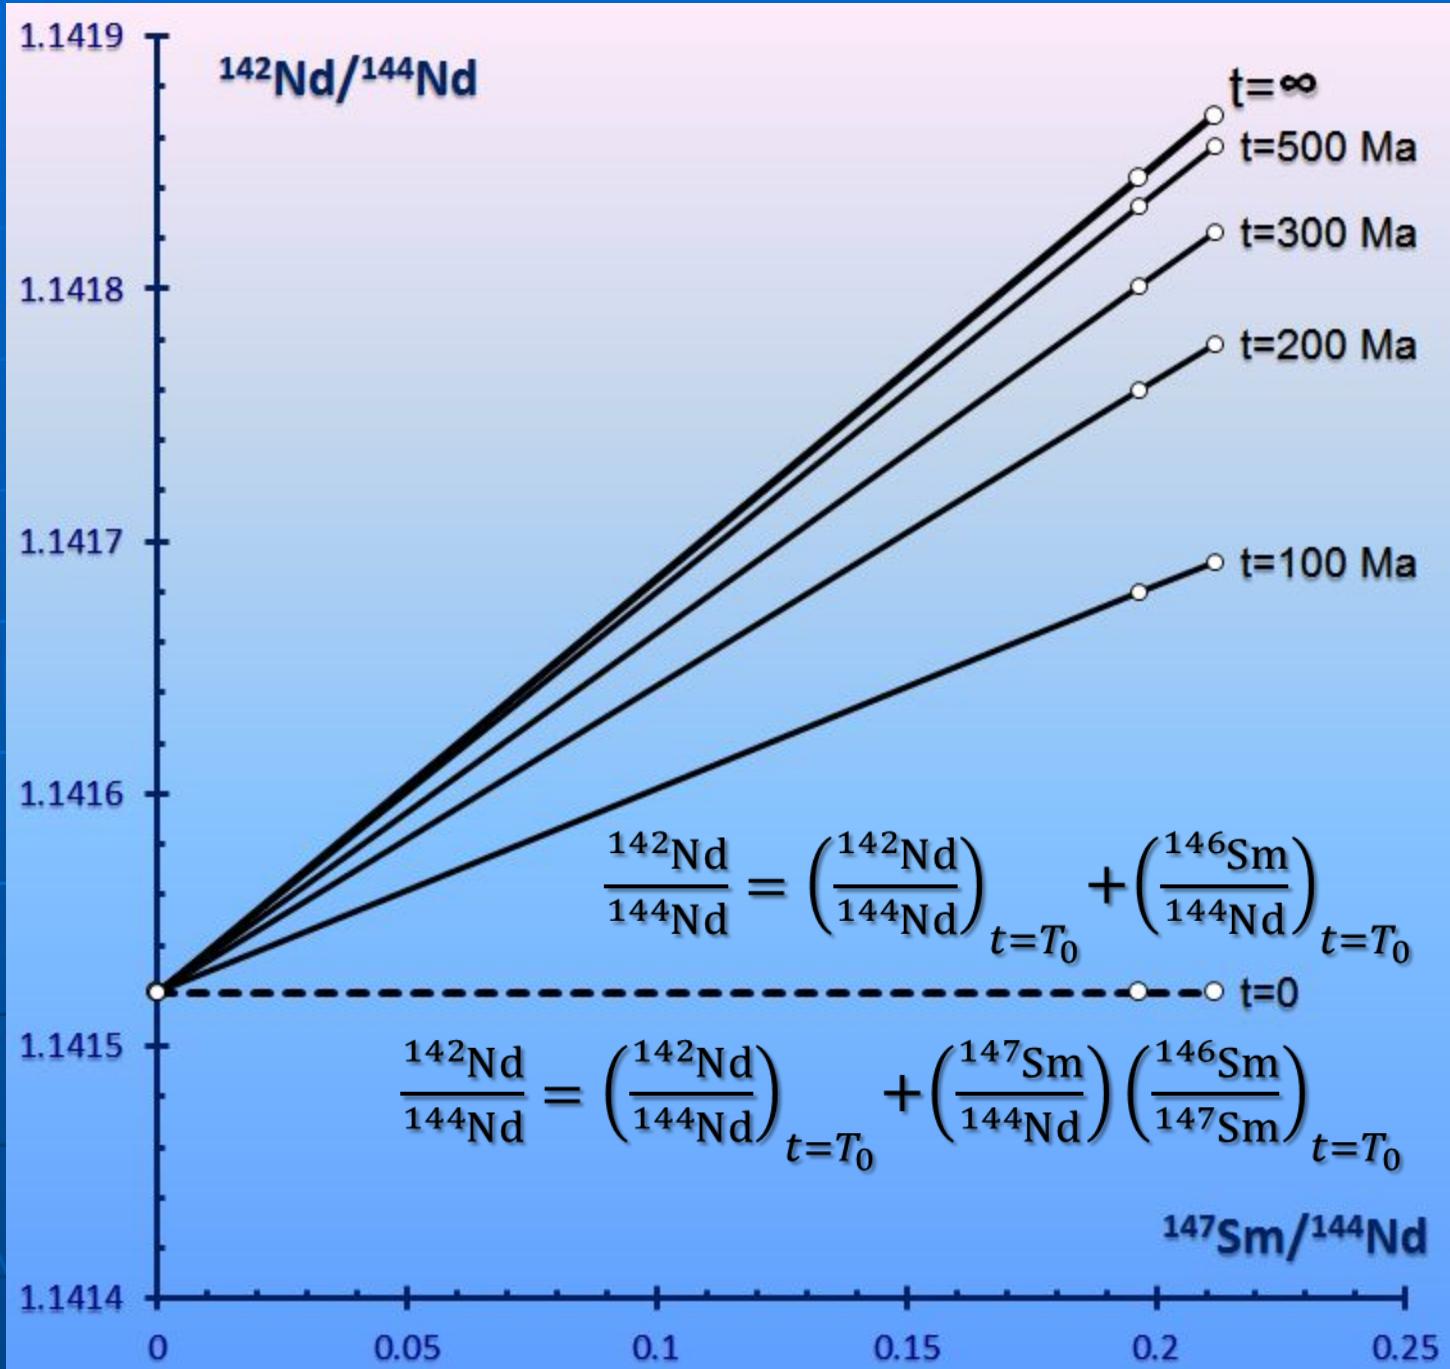

когда $t \gg T_{1/2}$

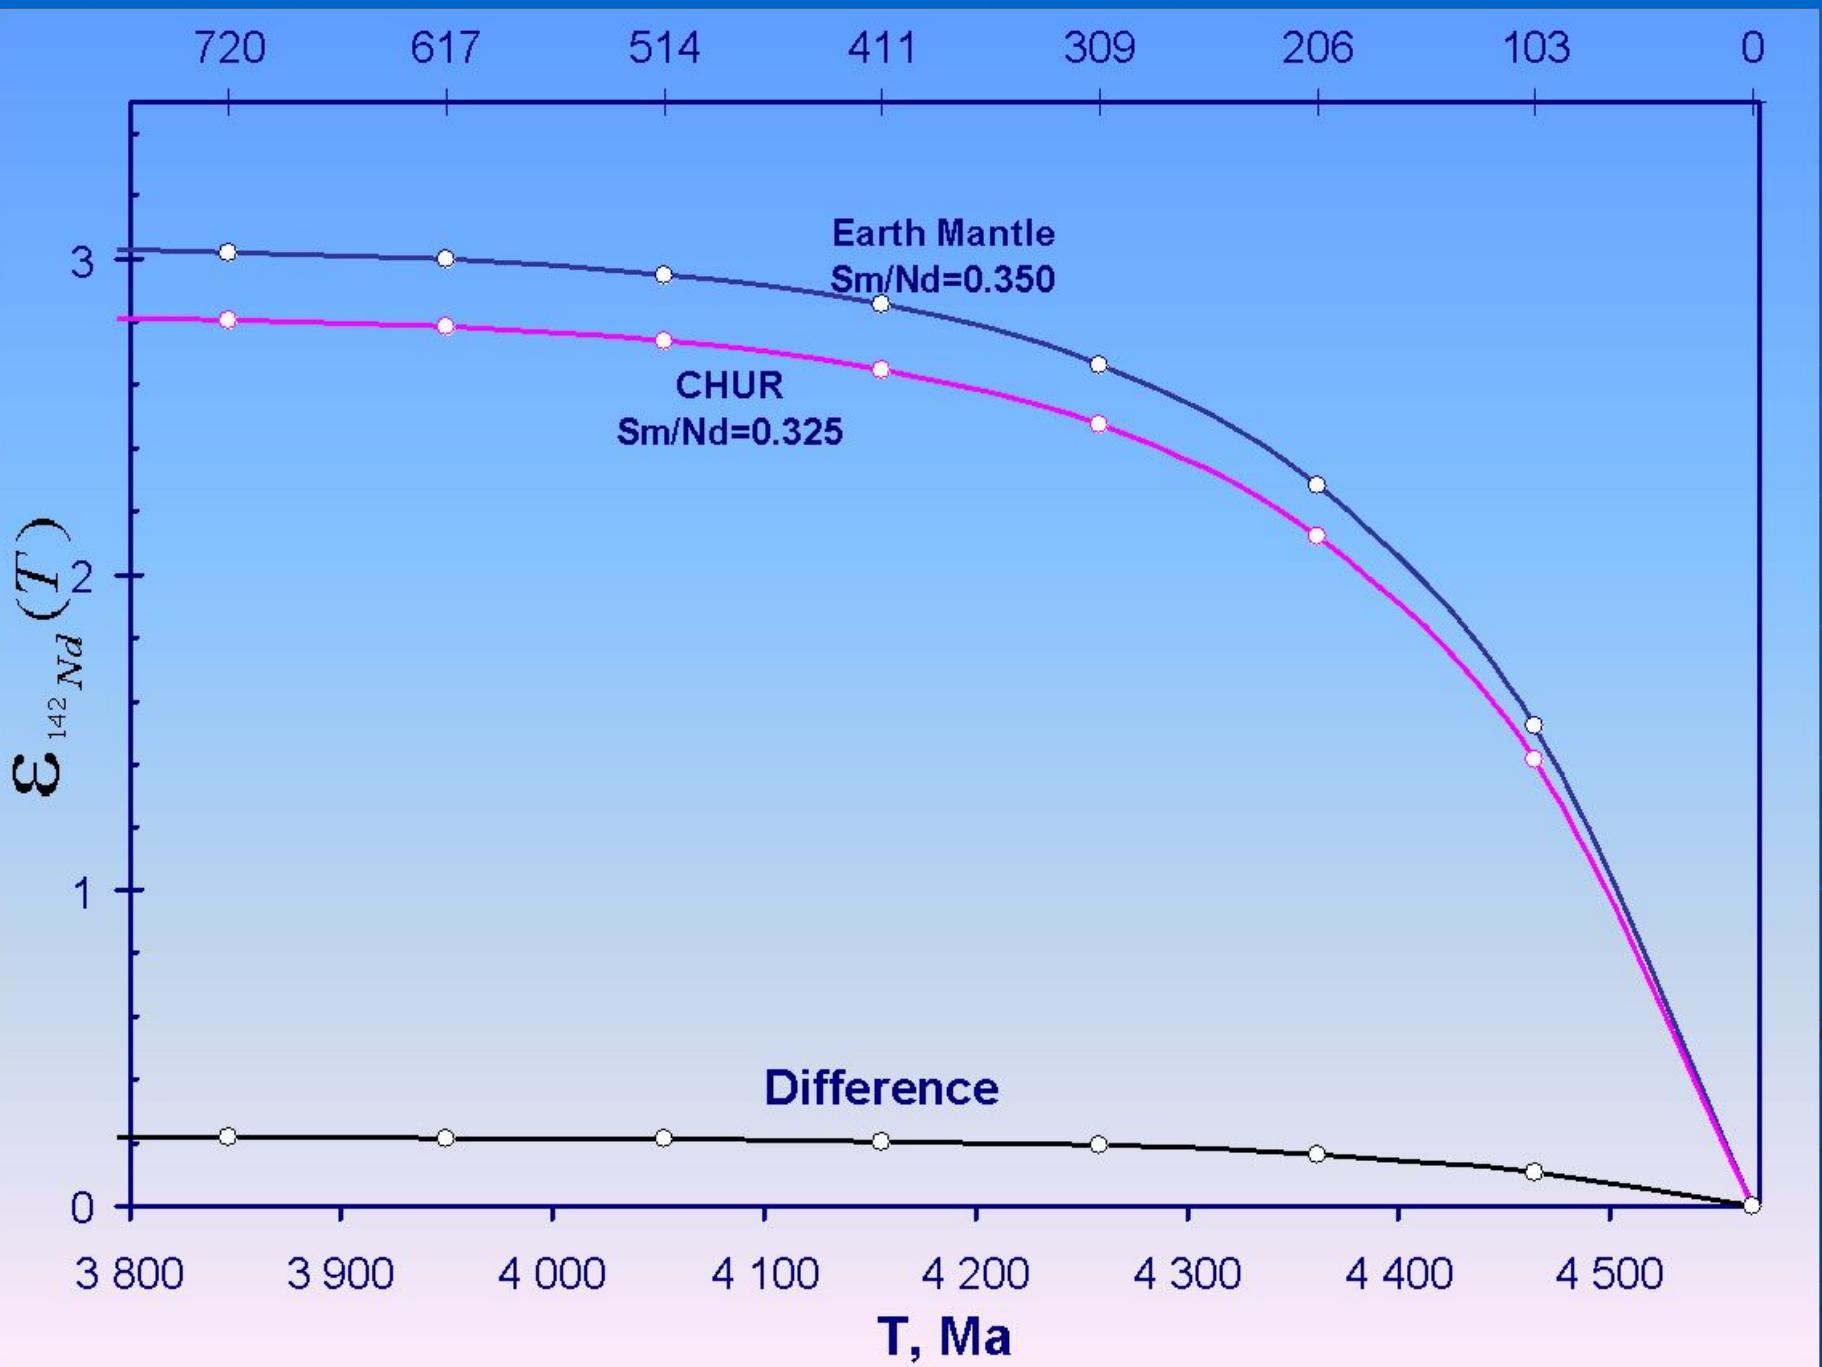

$$^{142}\text{Nd}_{\text{rad}} = ^{146}\text{Sm}_0$$

$$\left(\frac{^{142}\text{Nd}}{^{144}\text{Nd}} \right) = \left(\frac{^{142}\text{Nd}}{^{144}\text{Nd}} \right)_{t=T_0} + \left(\frac{^{146}\text{Sm}}{^{144}\text{Nd}} \right)_{t=T_0}$$

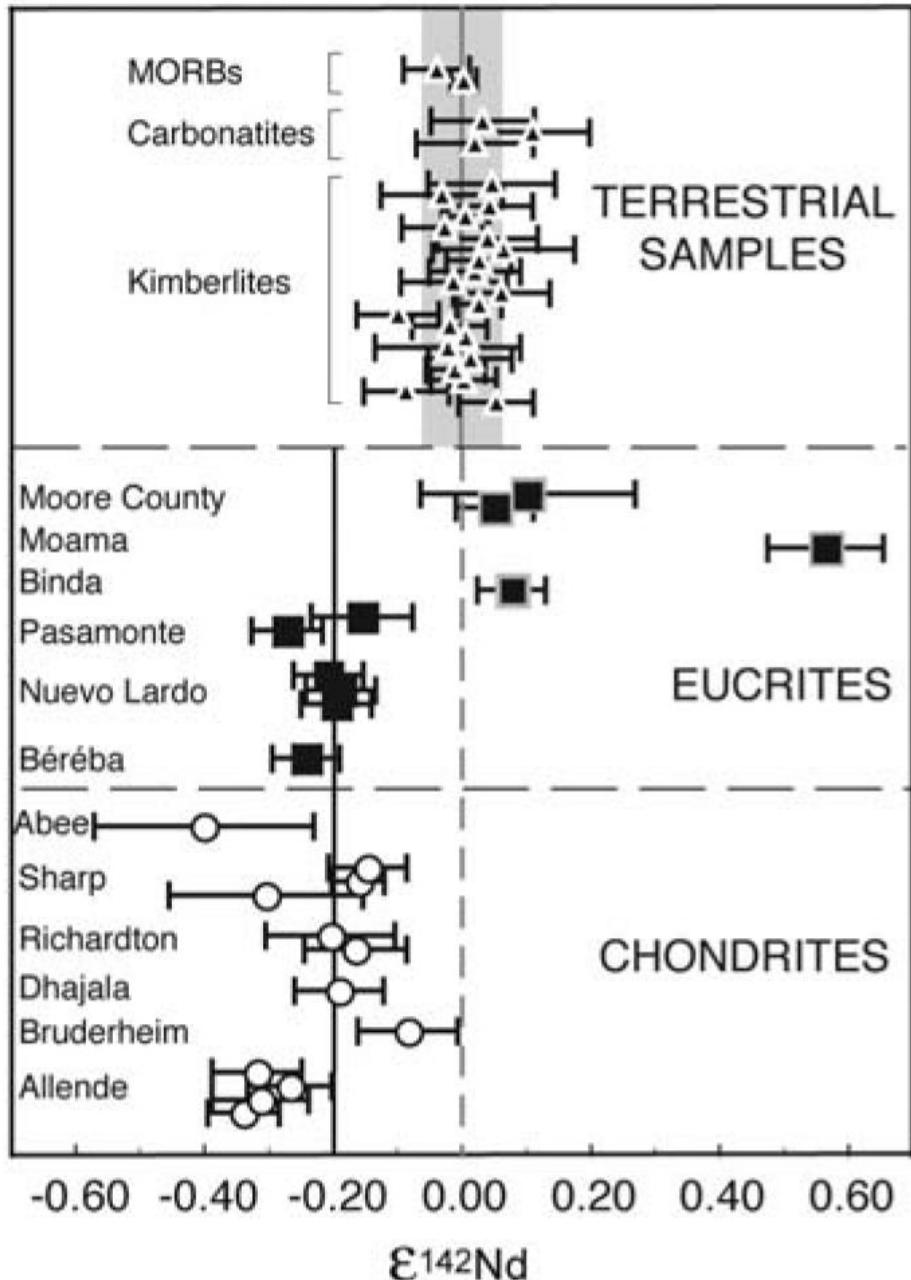

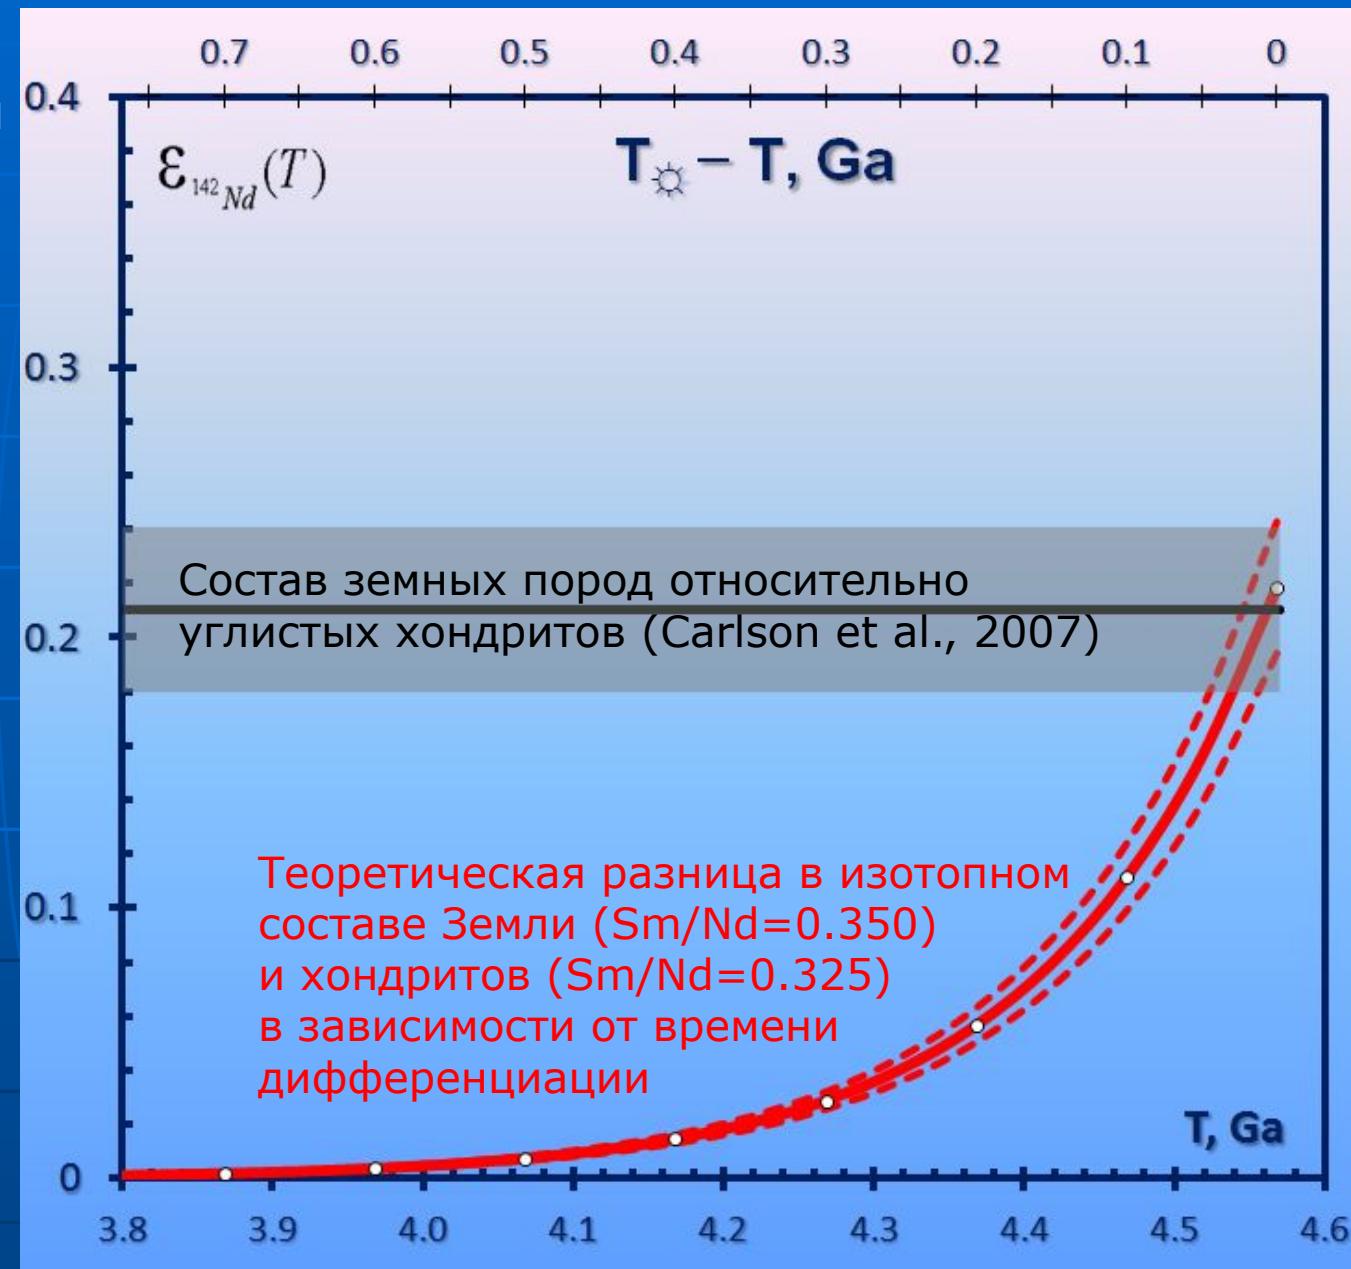

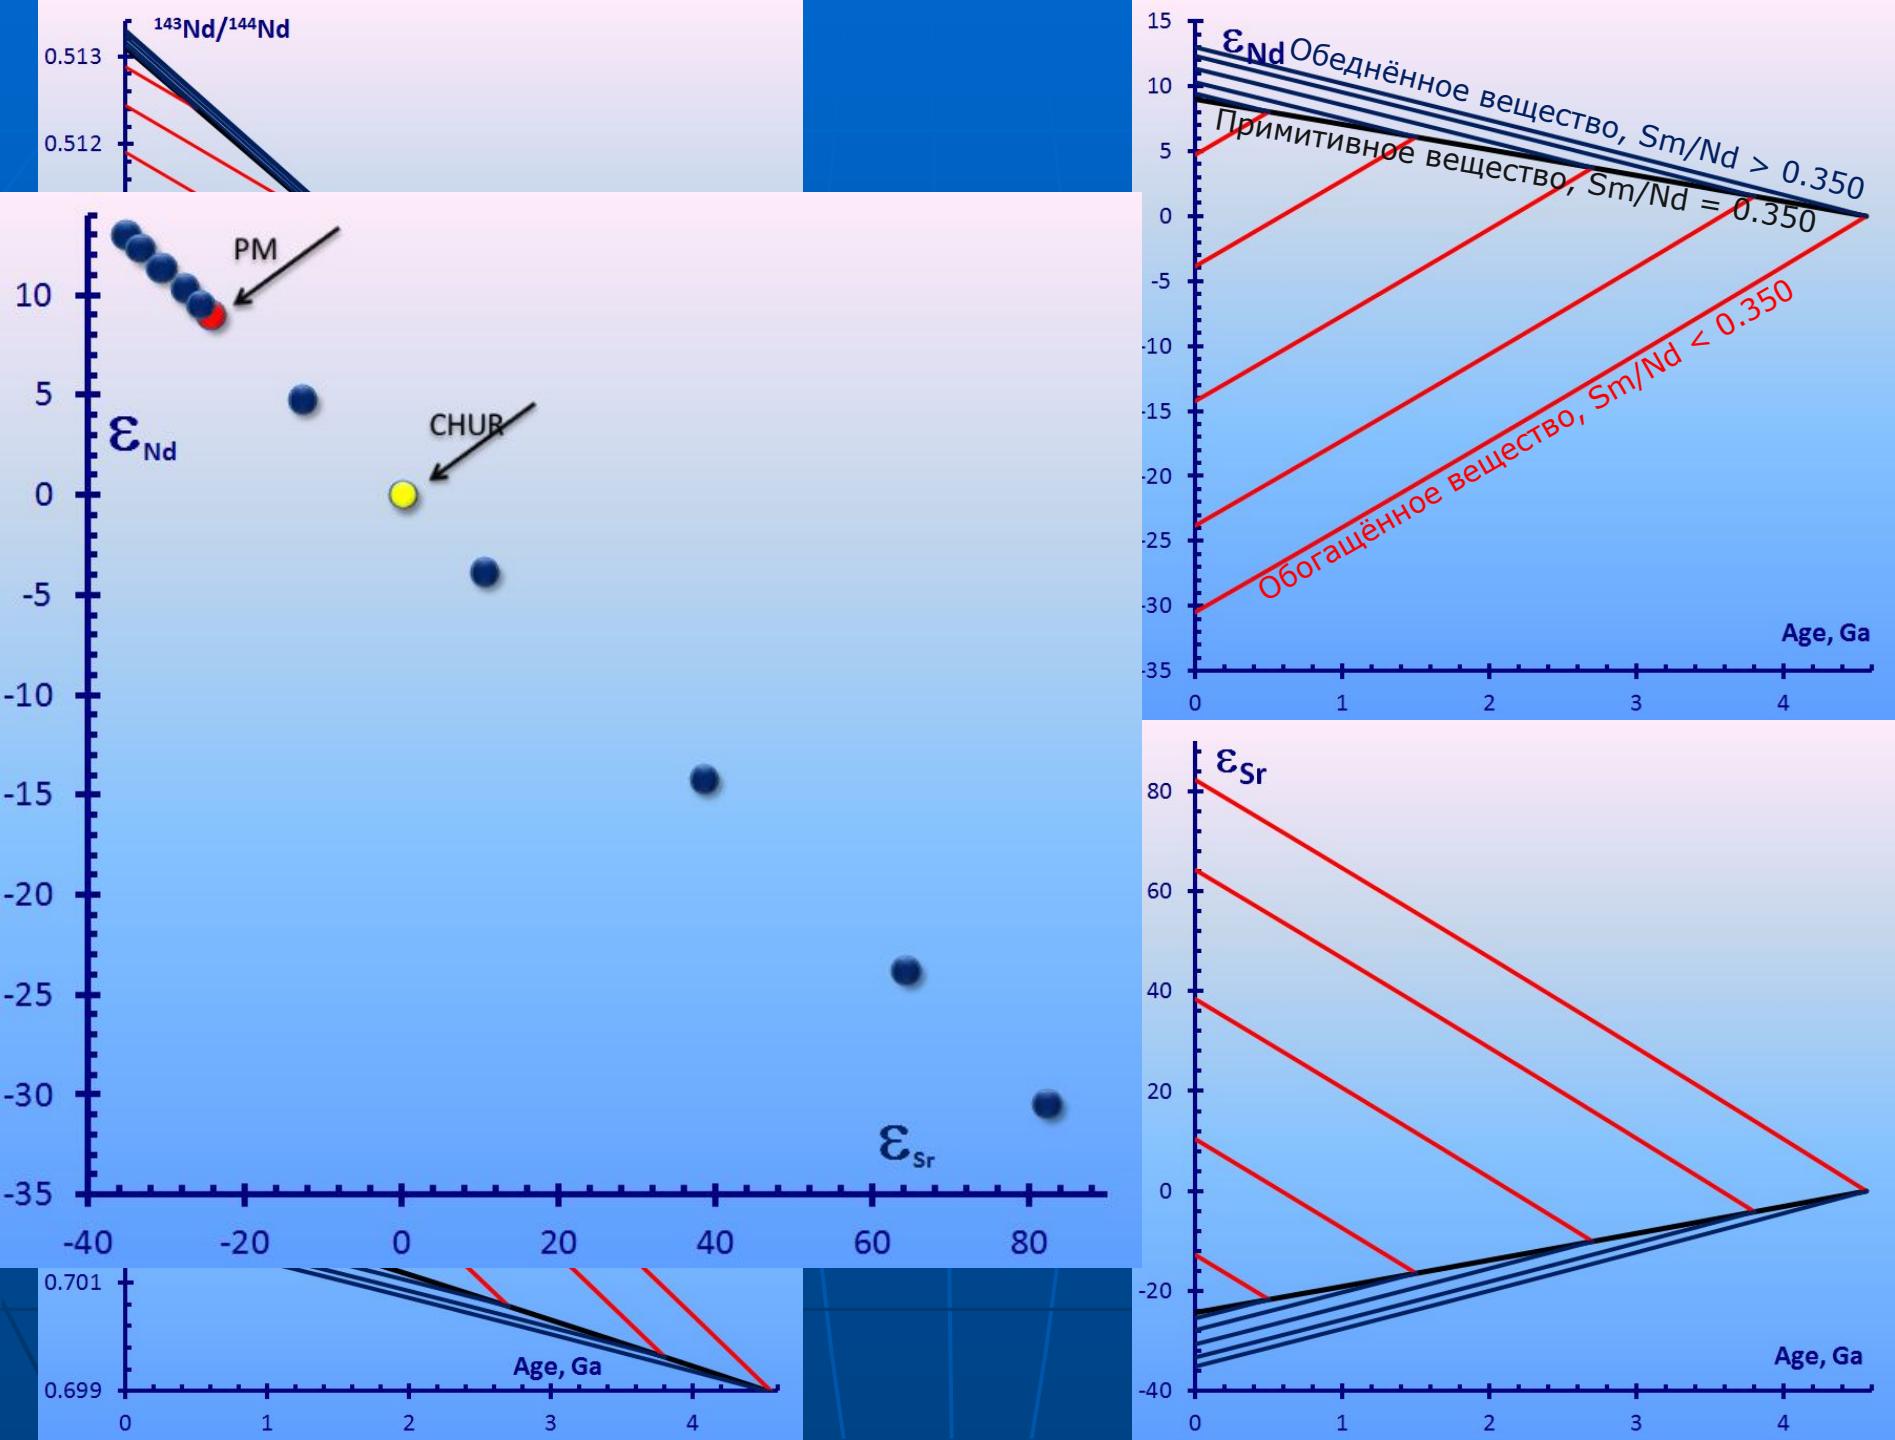

Fig. 1. $^{142}\text{Nd}/^{144}\text{Nd}$ ratios measured for chondrites and eucrites compared to the La Jolla terrestrial Nd standard ($\epsilon^{142}\text{Nd}$). All chondrites and basaltic eucrites have negative $\epsilon^{142}\text{Nd}$ values outside the external analytical error of $\pm 0.07 \epsilon$ units (2σ) (shaded area). Cumulate eucrites have positive $\epsilon^{142}\text{Nd}$ values in agreement with their high Sm/Nd, resulting from igneous processes on their parent body. The error bars correspond to the internal precision ($2\sigma_{\text{mean}}$). Terrestrial samples (MORBs, kimberlites, and carbonatites of different ages and collected in diverse locations) measured using the same procedure (27) have been added to demonstrate the significant excess of 0.2 ϵ units in all the terrestrial material (samples and standard) relative to the mean chondritic value. All terrestrial samples were measured several times using the same procedures as were used for the chondrites. The uncertainties reported on the mean are 2σ .

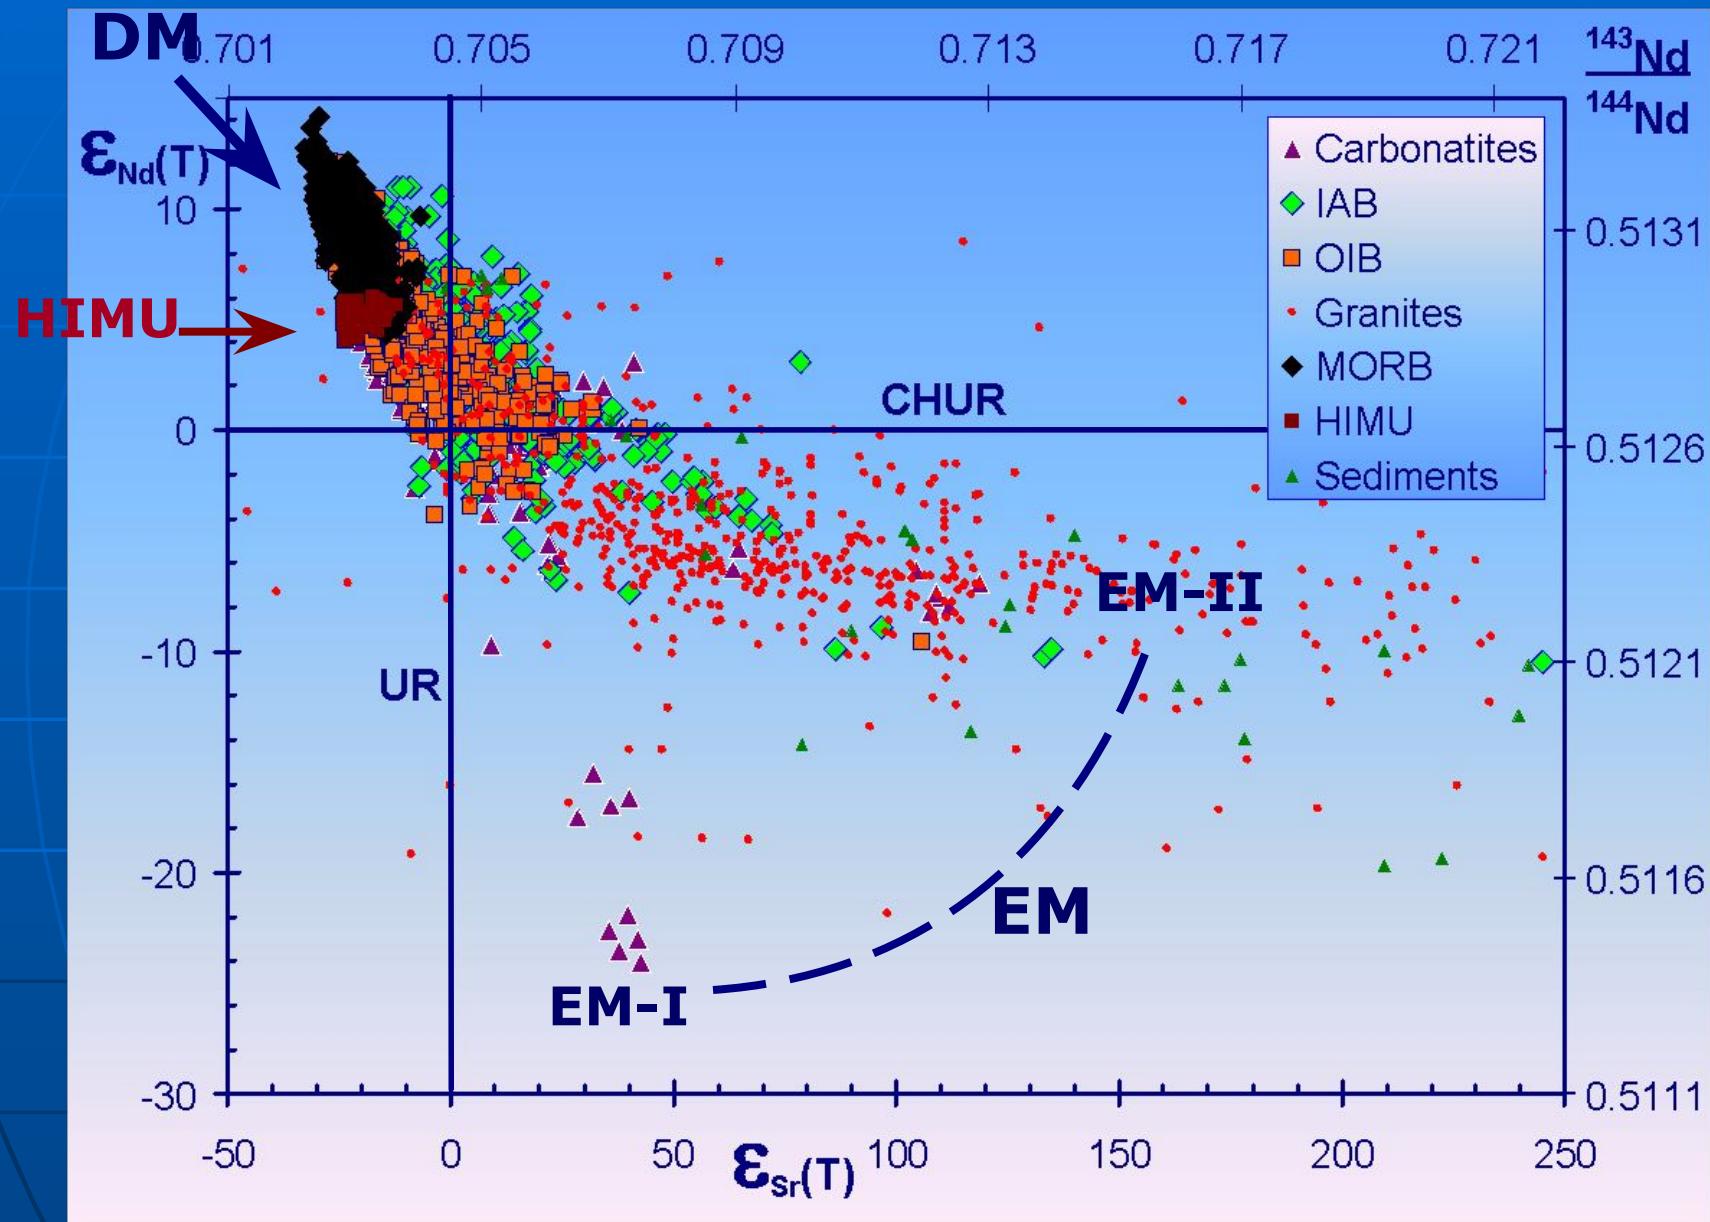

Различия в Sm/Nd отношениях Земли и хондритов возникли изначально. Корообразование к этому феномену отношения не имеет

Обе пары:

согласованным
выводам

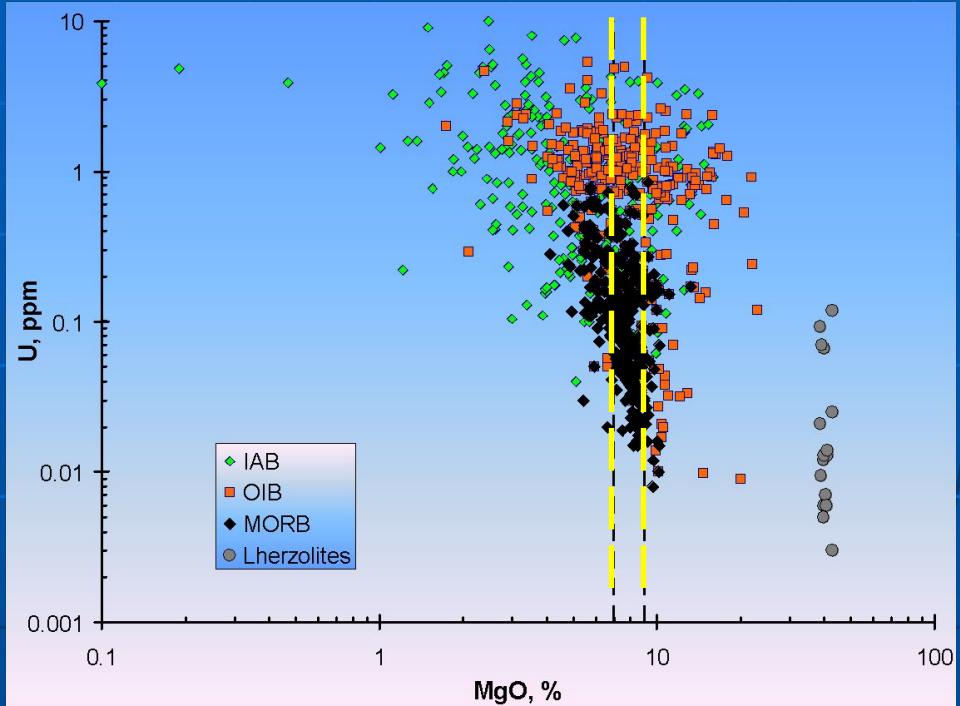

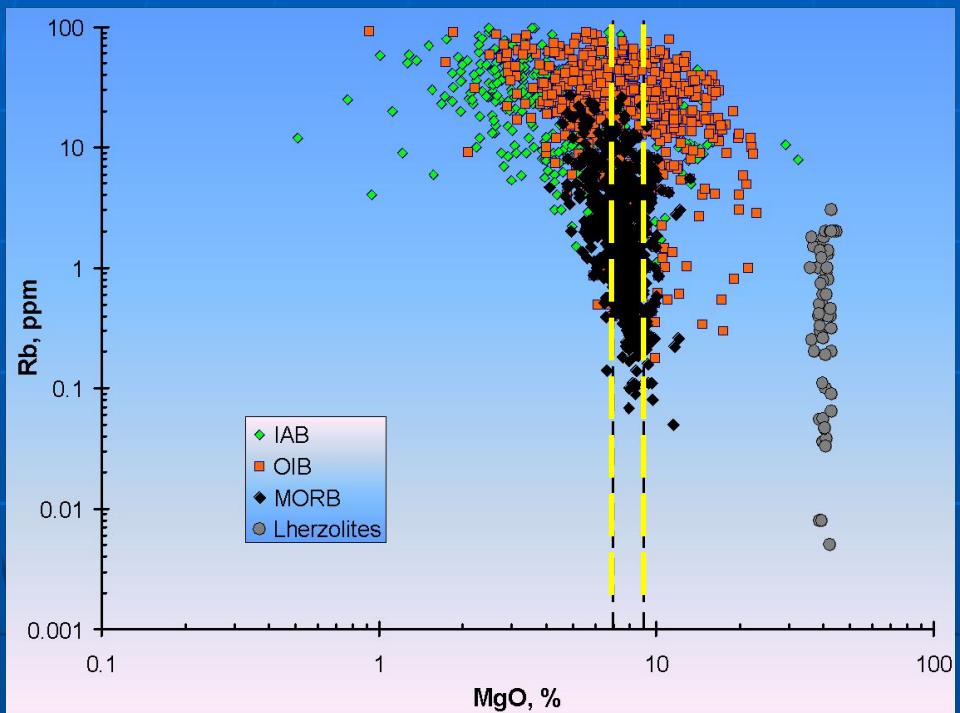

Причины изотопной гетерогенности мантии в Rb-Sr и Sm-Nd изотопных системах

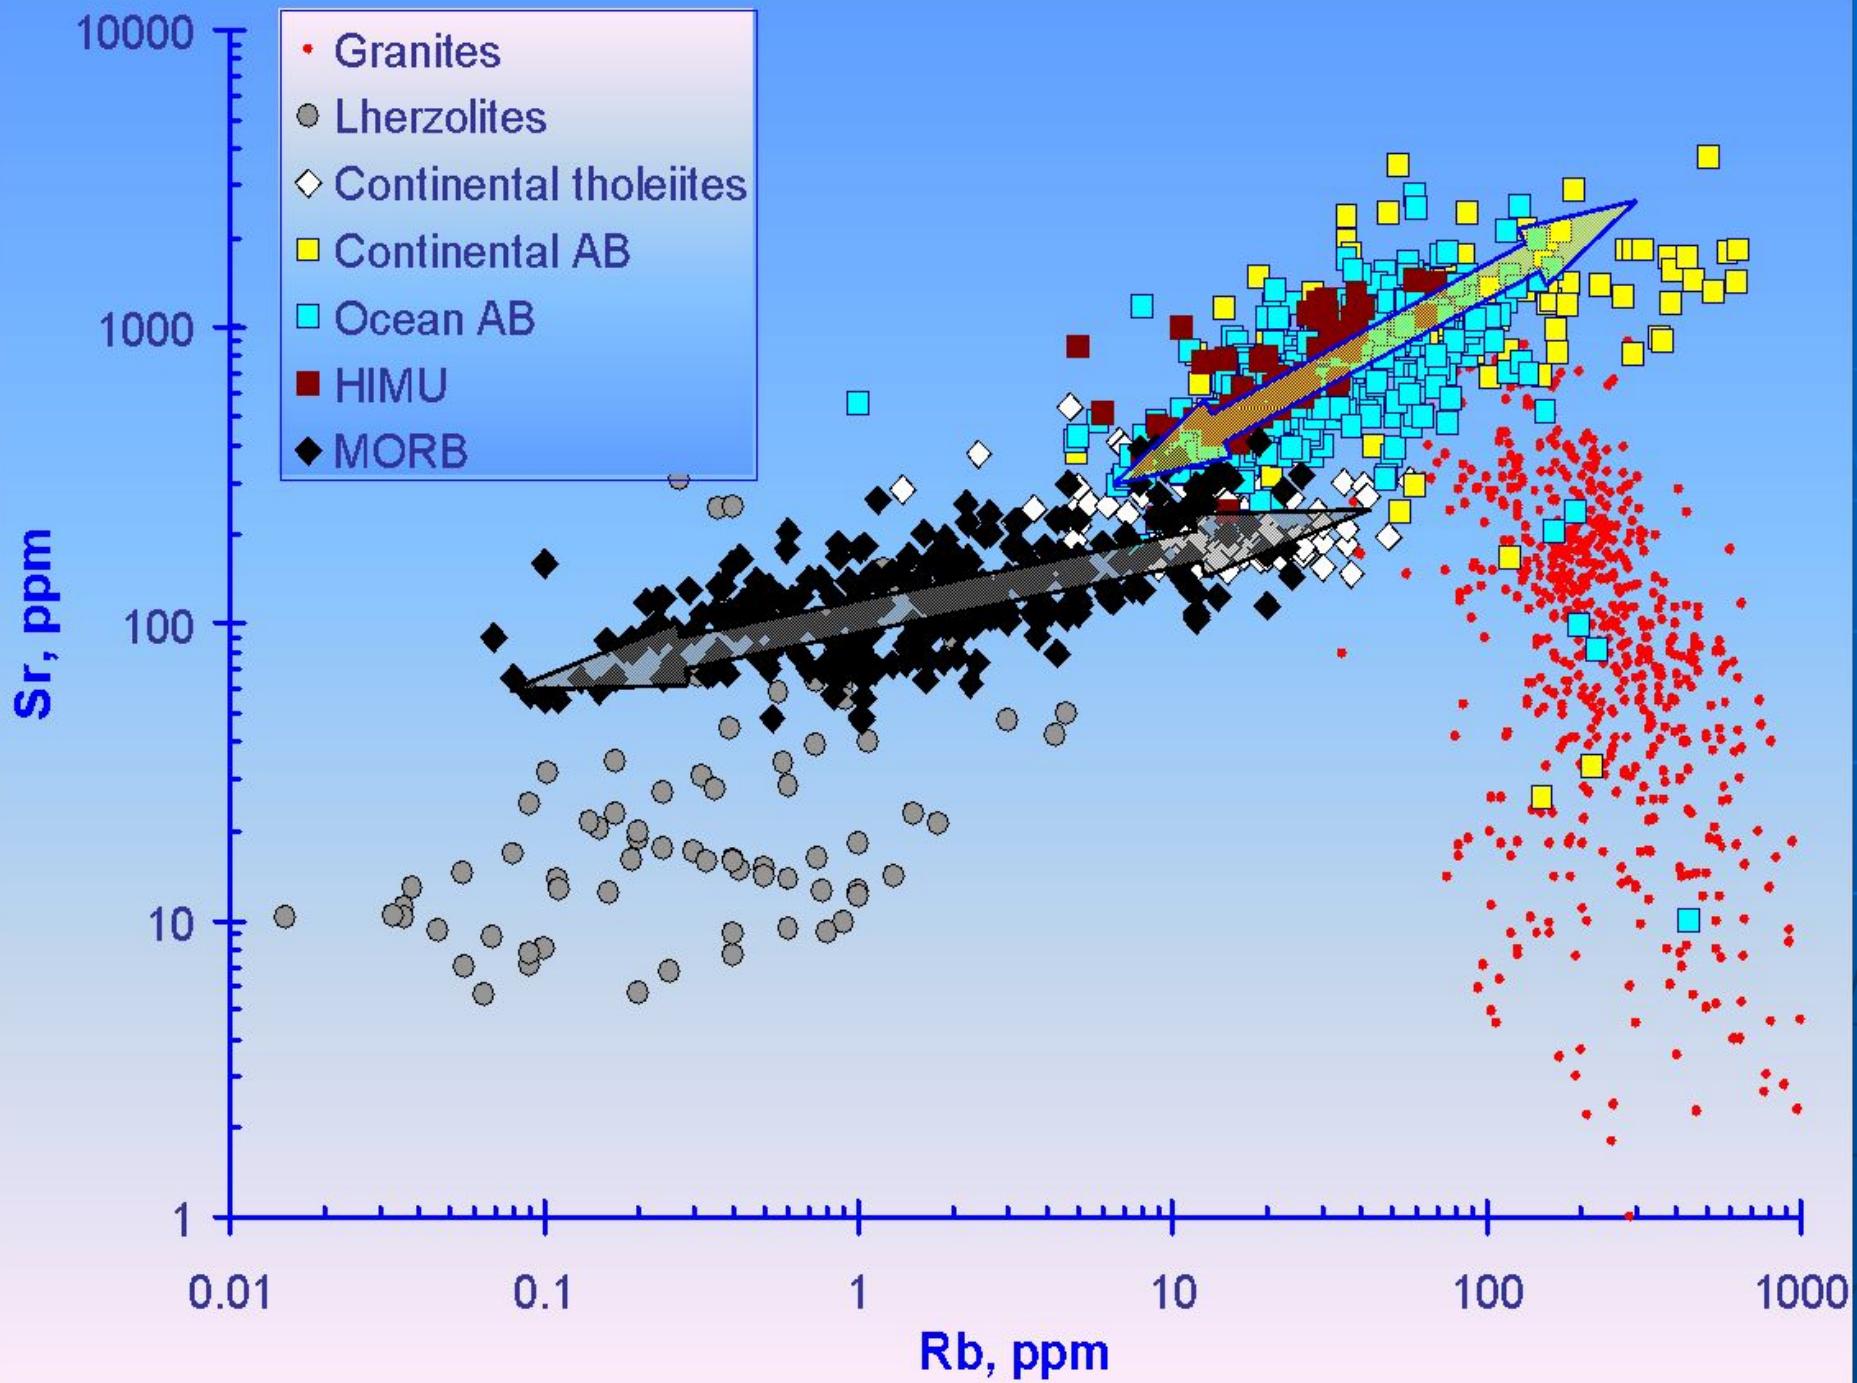

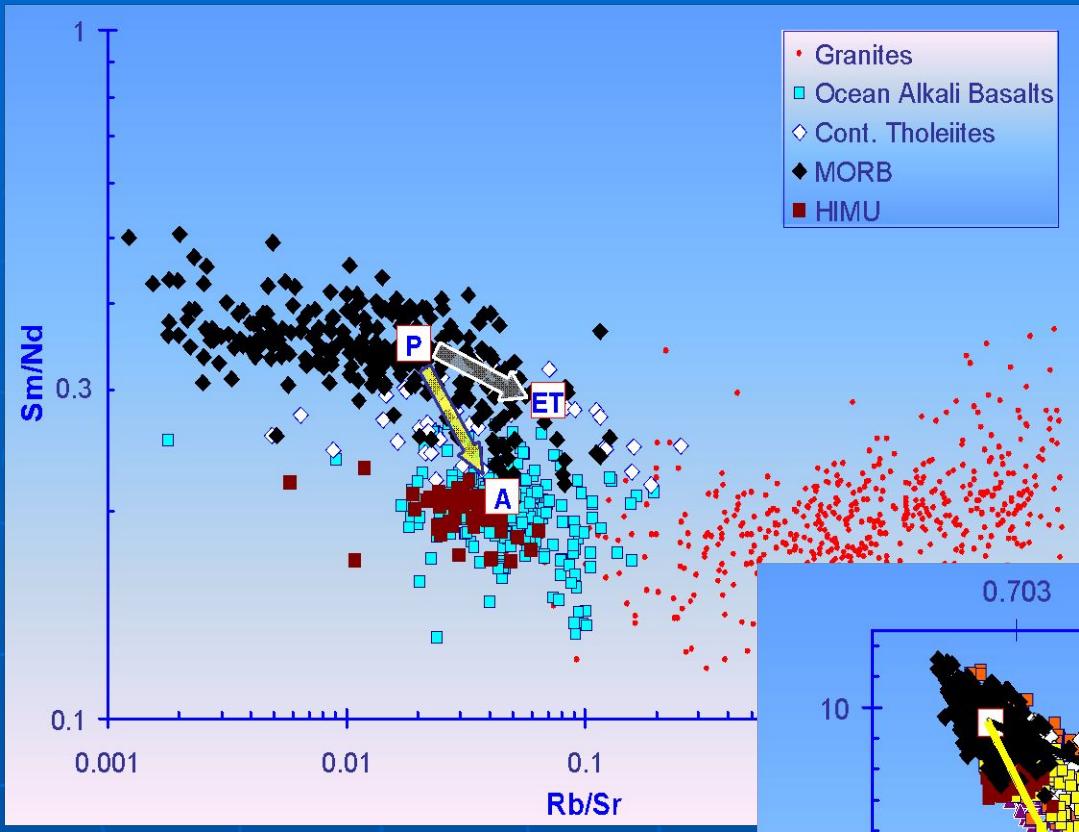

Насколько мантийный источник может быть гетерогенным в отношении элементов-примесей?

Если в мантии имеют место вариации Rb/Sr, Sm/Nd, U/Th/Pb, Lu/Hf отношений, то со временем это должно привести к изотопной гетерогенности Sr, Nd, Pb, Hf

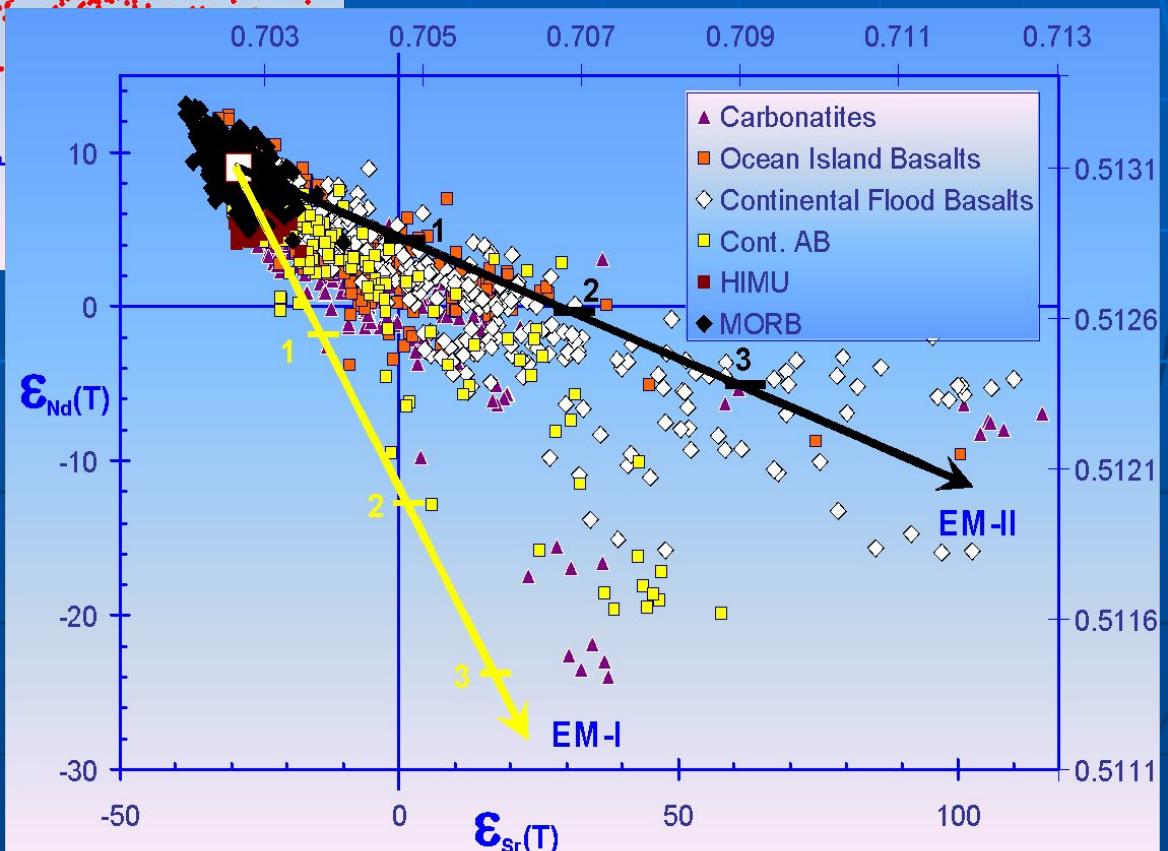

Два главных типа мантийных магм с “обогащёнными” характеристиками:

- Щелочные базальты (A)
- Обогащённые толеиты (ET)

Изотопная гетерогенность мантии ($^{87}\text{Sr}/^{86}\text{Sr}$ и $^{143}\text{Nd}/^{144}\text{Nd}$) может быть следствием её химической гетерогенности (Rb/Sr и Sm/Nd)
