

Web of Science: мировая практика применения индекса цитирования при проведении научных исследований

Павел Касьянов,
Региональный представитель

История ISI

- Идея индекса цитирования впервые предложена Ю. Гарфилдом в 1955м году
- ISI приобретён Thomson в 1992м году
- В настоящий момент – часть Thomson Reuters

Thomson Reuters

- Создана 17го апреля 2008г. в результате слияния Thomson Corporation и Reuters Group PLC.
- *“Thomson Reuters is the world’s leading source of intelligent information for businesses and professionals”*
- Более 50,000 сотрудников
- Представительства в 93х странах мира

Более 3,500+ клиентов *Web of Science* в 100 странах

Северная Америка
760 клиентов в 2
странах

Россия
147 клиентов

Европа, Ближний Восток и
Африка
2000+ клиентов в 50 странах

Латинская Америка
244 клиентов в 12 странах

Азия
353 клиентов в 26 странах

Как проводится оценка результатов научной деятельности?

- Комбинация различных методологий и подходов, например:
 - Количество и объём полученных грантов
 - Количество наград (например, Нобелевских премий)
 - Peer evaluation
 - **Подсчёт публикационной активности**
 - **Подсчёт объёма цитирования**
- Peer Evaluation - Дорого, субъективно, существенные временные затраты
- Ни один из этих показателей не работает идеально сам по себе, всегда есть «частные случаи» и необходима экспертная оценка для правильной интерпретации результатов

Растущий интерес к применению библиометрических методов

- Страны с существенным научным потенциалом активно используют библиометрические показатели при оценке результатов научной деятельности
- Сегодня во многих странах существуют целые команды аналитиков. Они подготавливают библиометрические отчёты, часто называемые «science indicators studies»
- Практически в 100% случаев, исследования проводятся на основе данных Thomson Reuters.

Некоторые правительственные органы, использующие наши данные

- США: National Institutes of Health
- США: National Science Foundation (с 1974)
- Великобритания: Office of Science & Technology; Higher Education Funding Council
- Евросоюз: DGXII (Research Directorate)
- Австралия: Академия Наук, правительственная лаборатория CSIRO
- Канада: NSERC, FRSQ (Quebec), Alberta Research Council
- Франция: Министерство Науки, OST - Париж, CNRS
- Германия: Общество Макса Планка, правительственные лаборатории, DKFZ, MDC
- Япония: Национальный институт Информатики, Министерство Образования, Министерство Экономики, Торговли и Промышленности
- Китай: Академия Наук

Политика отбора журналов в Web of Science

- Для чего мы отбираем журналы?

Относительно небольшая группа журналов публикует абсолютное большинство значимых научных результатов

Всего 3000 журналов покрывает 80% статей...

...но, что ещё более важно – 92% того, что цитируется

В 7,621 журнале опубликовано 814,967 статей, получивших 20,834,641 ссылок
4% журналов (300) публикуют 30% статей (239,206)
4% журналов (300) получают 51% ссылок (10,681,596)

Полезность и качество цитирования

- Для чего?
 - Ссылка на источник
 - Идентификация методологии
 - Предоставление читателю возможности ознакомиться с дополнительной информацией
 - Подтверждение данных
 - Исправление информации
 - Критика/комментарии к чьей-то работе или точке зрения
- Цитирование является индикатором полезности и авторитетности статьи и её влияния на научное сообщество; оно является показателем, по которому можно сравнить результаты исследования учёных

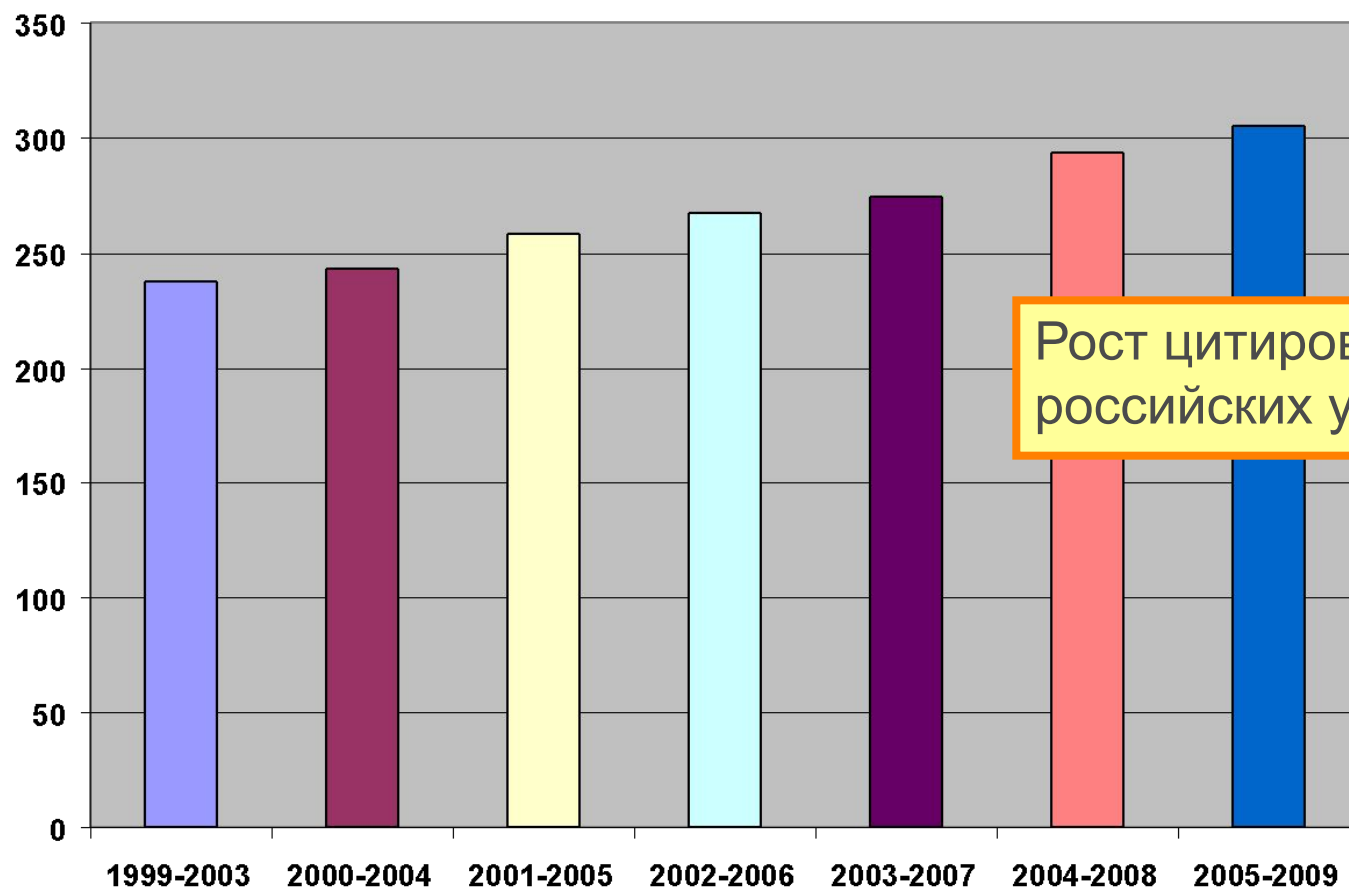

Политика отбора журналов в Web of Science

- Ежегодно рассматривается ~2000 журналов
 - 10-12% принимается
- Эксперты Thomson Reuters
 - Профессионалы информационного бизнеса
 - Библиотекари
 - Эксперты в конкретной предметной области

Оценка результатов исследований на национальном уровне

Эффективность – индекс Хирша

“...can be found very easily by ordering the papers by ‘times cited’ in the Thomson ISI Web of Science database.”

An index to quantify an individual's scientific research output

J. E. Hirsch

Department of Physics, University of California, San Diego
La Jolla, CA 92037-0219

I propose the index h , defined as the number of papers with citation number higher or equal to h , as a useful index to characterize the scientific output of a researcher.

PACS numbers:

For the few scientists that earn a Nobel prize, the impact and relevance of their research work is unquestionable. Among the rest of us, how does one quantify the cumulative impact and relevance of an individual's scientific research output? In a world of not unlimited resources such quantification (even if potentially distasteful) is often needed for evaluation and comparison purposes, eg for university faculty recruitment and advancement, award of grants, etc.

The publication record of an individual and the citation record are clearly data that contain useful information. That information includes the number (N_p) of papers published over n years, the number of citations (N_c^j) for each paper (j), the journals where the papers were published and their impact parameter, etc. This is a large amount of information that will be evaluated with different criteria by different people. Here I would like to propose a single number, the “ h -index”, as a particularly simple and useful way to characterize the scientific output of a researcher.

A scientist has index h if h of his/her N_p papers have at least h citations each, and the other ($N_p - h$) papers have no more than h citations each.

The research reported here concentrated on physicists, however I suggest that the h -index should be useful for other scientific disciplines as well. (At the end of the paper I discuss some observations for the h -index in biological sciences.) The highest h among physicists appears to be E. Witten's, $h = 110$. That is, Witten has written 110 papers with at least 110 citations each. That gives a lower bound on the total number of citations to Witten's papers at $h = 12,100$. Of course the total number of citations ($N_{c,tot}$) will usually be much larger than h^2 , since h^2 both underestimates the total number of citations of the h most cited papers and ignores the papers with fewer than h citations. The relation between $N_{c,tot}$ and h will depend on the detailed form of the particular distribution [1, 2], and it is useful to define the proportionality constant a as

$$N_{c,tot} = ah^2. \quad (1)$$

I find empirically that a ranges between 3 and 5.

Other prominent physicists with high h 's are A.J. Heeger ($h = 107$), M.L. Cohen ($h = 94$), A.C. Goswami ($h = 94$), P.W. Anderson ($h = 91$), S. Weinberg

($h = 75$), D.J. Scalapino ($h = 75$), G. Parisi ($h = 73$), S.G. Louie ($h = 70$), R. Jaekiw ($h = 69$), F. Wilczek ($h = 68$), C. Vafa ($h = 66$), M.B. Maple ($h = 66$), D.J. Gross ($h = 66$), M.S. Dresselhaus ($h = 62$), S.W. Hawking ($h = 62$).

I argue that h is preferable to other single-number criteria commonly used to evaluate scientific output of a researcher, as follows:

(0) Total number of papers (N_p): Advantage: measures productivity. Disadvantage: does not measure importance nor impact of papers.

(1) Total number of citations ($N_{c,tot}$): Advantage: measures total impact. Disadvantage: hard to find; may be inflated by a small number of ‘big hits’, which may not be representative of the individual if he/she is coauthor with many others on those papers. In such cases the relation Eq. (1) will imply a very atypical value of a , larger than 5. Another disadvantage is that $N_{c,tot}$ gives undue weight to highly cited review articles versus original research contributions.

(2) Citations per paper, i.e. ratio of $N_{c,tot}$ to N_p : Advantage: allows comparison of scientists of different ages. Disadvantage: hard to find; rewards low productivity, penalizes high productivity.

(3) Number of ‘significant papers’, defined as the number of papers with more than y citations, for example $y = 50$. Advantage: eliminates the disadvantages of criteria (0), (1), (2), gives an idea of broad and sustained impact. Disadvantage: y is arbitrary and will randomly favor or disfavor individuals; y needs to be adjusted for different levels of seniority.

(4) Number of citations to each of the q most cited papers, for example $q = 5$. Advantage: overcomes many of the disadvantages of the criteria above. Disadvantage: it is not a single number, making it more difficult to obtain and compare. Also, q is arbitrary and will randomly favor and disfavor individuals.

Instead, the proposed h -index measures the broad impact of an individual's work; it avoids all the disadvantages of the criteria listed above; it usually can be found very easily, by ordering papers by ‘times cited’ in the Thomson ISI Web of Science database [3]; it gives a ballpark estimate of the total number of citations, Eq. (1).

Thus I argue that two individuals with similar h are

Abstract: The high precision X-ray spectroscopy studies of plasma created from the CO₂ clusters in gas jet targets by the ultrashort laser pulses (35 and 60 A duration) were performed at the intensities I-L similar to 10⁽¹⁷⁾-10⁽¹⁸⁾ W cm⁽⁻²⁾. The spectral line shape of the H-like and He-like oxygen ions gains an asymmetry with increasing the laser pulse intensity. Theoretical modeling of the line shape shows that the asymmetry can be explained by absorption of the Doppler-shifted line radiation from the essential fraction of ions (over 10⁽⁻³⁾) with energies above 1 MeV due to photoionization of inner shells of carbon ions. The results obtained demonstrate measurement capabilities of the X-ray spectral measurements of multicharged ions accelerated during the interaction with a laser radiation.
