Internet Peering Ecosystem

The internet's undersea world

The vast majority of the world's communications are not carried by satellites but an altogether older technology: cables under the earth's oceans. As a ship accidentally wipes out Asia's net access, this map shows how we rely on collections of wires of less than 1cm diameter to link us all together

Fibre-optic submarine cable systems

In-service
Planned
Damaged

Cables with a minimum capacity of 100 Gbps are marked under construction or pending (year-end 2007)

Internet users affected by the Alexandria accident

The main countries affected in Wednesday's event

World cable capacity

Submarine cable operators light (turn on) capacity on their systems to sell bandwidth to other carriers. Carriers buy extra capacity, mainly to hold in reserve. On the trans-Atlantic route 80% of the bandwidth is purchased, but only 29% is used

Capacity in terbytes a second

What makes up "used capacity"?

The longest submarine cables

The SeaMeWe-3 system from Norden in Germany to Rango, South Korea connects 30 different countries with 30 landing points

SeaMeWe-3	39,000 km
Southern Cross	30,500 km
China-ITS	30,476 km
FLAG Europe-Asia	28,000 km
South America-1	25,000 km

The world's cables in bandwidth

The first intercontinental telephony submarine cable system, TAT-1, connected North America to Europe in 1958 and had an initial capacity of 640,000 bytes per second. Since then, total trans-Atlantic cable capacity has soared to over 7 trillion bps

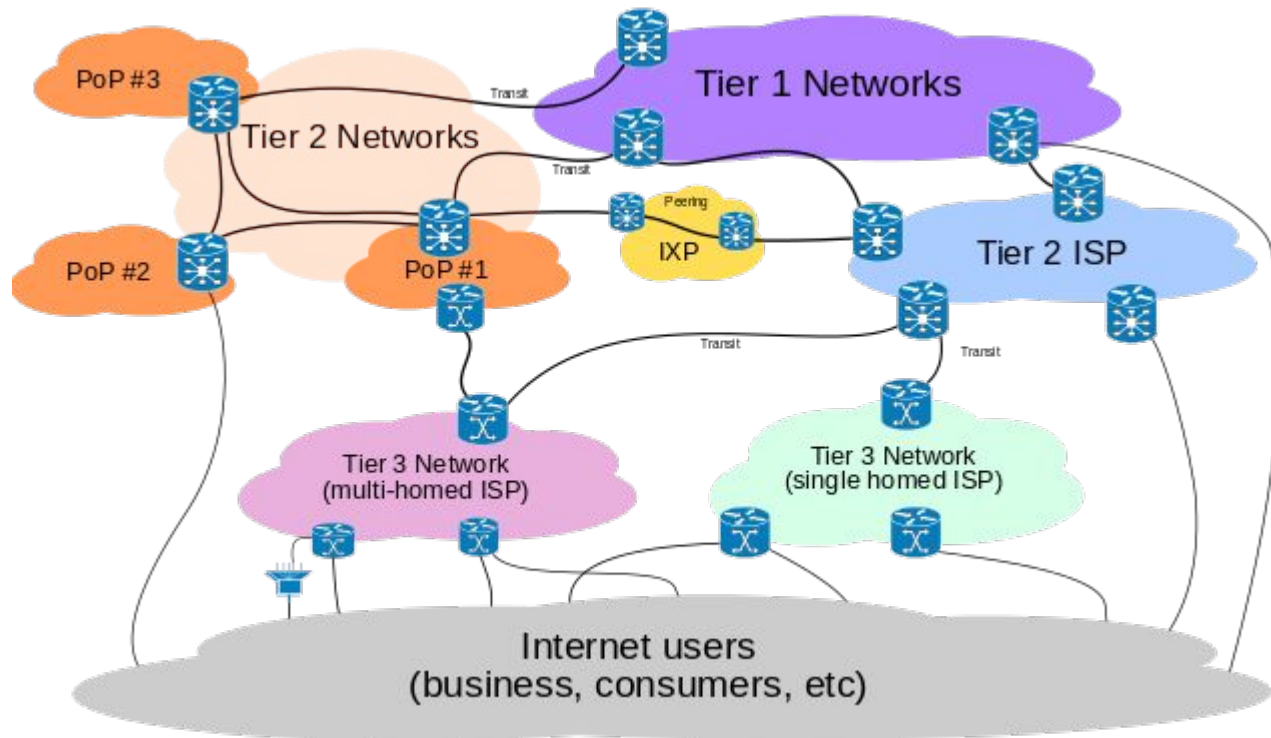

Cross-section of a cable

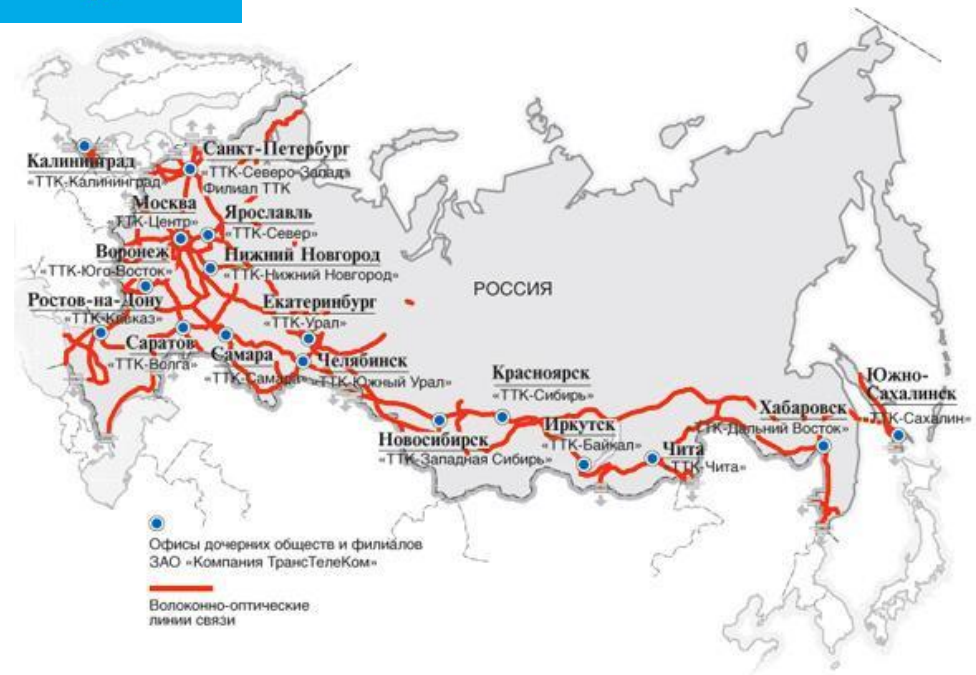

Cables of this strength are typically 60 mm in diameter and weigh over 10,000 kilograms a kilometer. In deeper waters, lighter and less insulated cables are used

Redefining Flow Label in IPv6 and MPLS Headers for End to End QoS in Virtual Networking for Thin Client

Abstract— Applications that require timeliness such as; video conferencing, Voice over IP (VoIP), Video-on-Demand (VoD) etc., require quantified and well managed Quality of Service (QoS). For this, the flow label field in IPv6 header and the Label field in MPLS header should be used for efficient QoS provisioning. In this paper, flow label specifications were first investigated and then a new structure is proposed for QoS provisioning. The 20-bit field in IPv6 as well as MPLS is meant to provide QoS, other than labeling or identification purpose. But its usage is not standardized and defined that how these 20-bits must effectively be used to provide maximum possible QoS in a better way. This paper discusses it by proposing portions for QoS by explicitly specifying bandwidth, delay, and packet loss. By keeping the QoS parameters open in this way, it would be easy for a flow to decide what to reserve and how much to reserve. After that, mapping of flow label with class fields of IPv6 and MPLS is presented. In virtual networks, specially for Thin client, service quality degradation is a major issue, when IPv4-IPv6 virtual networks co-exist. This is also where this redefinition can come very handy.

Keywords—Flow label; IPv6; MPLS; QoS; virtual networking; Thin client

is considered to be the best available and most efficient combination of protocols on layer 2 and layer 3 for routing of packets. So, the same specification of label field can be used with both these protocols to allow the stability in QoS for a particular flow, throughout the communication, from MAC to the network layer. A 'flow' can be defined as a sequence of packets sent from a particular source to a particular (unicast or multicast) destination for which the source desires special handling for QoS by the intermediate routers [8]. The flow is uniquely identified within the network by the flow label and its source address. All packets belonging to one flow should be treated within the network in the same way. The usage of the flow label is not completely specified within the RFCs [8] and [9]. However the flow label field can be defined as a 20-bit field that may be used by a source to label sequences of packets for which it requests special handling by the routers, such as non-default quality of service or real-time service [8]. During our studies [15, 16], it was realized that in virtual networking environment, when IPv4 and IPv6 coexist, it incurs some reasonable amount of signaling overhead, due to which, service quality degrades. Since, redefinition of flow label for end to end QoS is the main concern of this paper and

Некоторые из этих механизмов инкапсулируют IPv6-пакеты внутри IPv4-пакетов.

Есть желание посмотреть, что на самом деле передается внутри IPv4-пакета (вложенный внутри IPv6-пакет – тоже часть IPv6-трафика, который необходимо учитывать при анализе). Каким образом может быть инкапсулирован IPv6 в IPv4?

Каким образом IPv6-трафик присутствует в IPv4-

[2001::1]:8080 == 1.1.1.1:8080

4

Согласно RFC6145 заголовок IPv6 **конвертируется** в IPv4. Пакет IPv6 превращается в IPv4 и высылается через IPv4 интерфейс NAT64:

Monitoring of Tunneled IPv6 Traffic Using Packet Decapsulation and IPFIX

By Martin Elich, Matej Gregr and Pavel Celeda

Internet Protocol Flow Information Export

Протокол IETF, определяющий стандарт экспорта информации о **потоках данных** с различных сетевых устройств.

Основан на протоколе Cisco NetFlow v9.

Информация о потоках данных может использоваться в таких задачах, как:

- Мониторинг трафика, учет использования сетевых ресурсов
- Анализ трафика
- Обнаружение/предотвращение вторжений

Кратко о

Получение статистики по IPv6-трафику, инкапсулированному в IPv4 (разбор некоторых туннелей)

Сборщик IPFIX (в данном случае Flowmon) собирает итоговую статистику по потокам со всех экспортеров и презентует ее пользователю в том или ином виде

Информация о потоке передается сборщику при помощи протокола IPFIX.

При обнаружении IPv6-пакета внутри IPv4, IPv6-пакет декапсулируется из IPv4, на основании информации в заголовке IPv6 пакет сопоставляется определенному потоку.

Пакеты распределяются по обработчикам
На каждом ядре сидит экспортер с самописным плагином для обнаружения IPv6 в v4 (реализовано обнаружение Teredo, ISATAP, 6to4)

В сети практически нет информации по библиотеке Skoree всего, с ее помощью делается zero-copy

Для каждого принятого пакета ставит timestamp
Некоторым образом получает хэш заголовка пакета
Далее согласно хэшу пакеты распределяются по обработчикам
